WAR INJURIES OF THE LUNGS

IT is wise to remember, as Sir Joseph Barcroft pointed out in opening the discussion on lung injuries at Porton reported in our columns last week (p 197), that while the aerial offensive on England has not as yet included gas attacks, not only H E but gas bombs may be used in future raids Both can cause lung injuries, and the discussion concerned itself with the clinical differentiation of the two types of pulmonary damage Those who took part agreed that histologically the differentiation is relatively straightforward Gases which act on the lungs cause bronchial spasm, destroy the bronchial mucous membrane, damage the alveolar walls, and produce acute pulmonary œdema Pulmonary damage which occurs as a result of H E explosions takes the form of hæmorrhagic lesions, which may be associated with signs of pulmonary fat embolism, and occasionally with those of carbon-monoxide poisoning It is to be hoped that future events—if they materialise—will justify the optimism of the participants in the discussion, and that it will be as simple to make a differential clinical diagnosis of nonfatal forms of lung damage as it is to differentiate them histologically in the dead At present it is undoubtedly true that not enough is generally known about the pulmonary changes which occur in H E incidents to distinguish the factors which may be responsible for different types of lung damage However obvious it may sound, Professor Ryle's suggestion that the differentiation of pulmonary injuries would be assisted by the knowledge of the history of the incidents responsible for them should be firmly borne in mind, to help in distinguishing not only gas injury from H E injury but also one form of H E injury from another The lack of such histories may well make the problem of a combination of gas and H E injury in the same casualties not just " more complex " as Prof Shaw Dunn remarked, but completely insoluble

THE AUTONOMIC NERVOUS SYSTEM

THE sympathetic chain was so called because of its numerous connexions with other nerves It was supposed to be the major factor in mediating " sympathies," or reactions accompanying but bearing no direct relation to the main reaction, an example being the pupillary constriction in a blind eye accompanying the constriction in the illuminated seeing eye " Sympathetic " has now become a purely anatomical term, applied to the autonomic outflow from the thoracic and lumbar segments The term parasympathetic, also anatomical, refers to the cranial and sacral outflows which overlap the sympathetic peripherally, acting usually in the opposite sense One of the outstanding discoveries of the last twenty years has been that autonomic postganglionic fibres can be classified on a physiological basis into those which act by liberating acetylcholine (cholinergic) and those which liberate an adrenaline like substance (adrenergic) at the effector organ The partition between cholinergic and adrenergic corresponds roughly, but not exactly, to the parasympathetic and sympathetic systems respectively In a historical survey and a later review[1] of modern work on the autonomic Sheehan points out that, concurrently with these studies of humoral transmission of impulses, there has been a growing realisation that the autonomic is not a system on its own, it has not only intimate associations with the spinal cord, of which it is an outgrowth, but important connexions with higher centres, to which it is subordinate Interest at present centres chiefly in the hypothalamus, but there is no doubt that the cerebrum, especially the precentral cortex, also influences the autonomic The activity of any group of cells in the central nervous system depends on the intensity of its " excitatory state." Such a group might have either a predominantly visceral or a predominantly somatic function yet its final activity might be determined—perhaps raised above a significant threshold—by a quite subsidiary access of excitation from the complementary source This seems further evidence that the autonomic and somatic nervous systems are inseparable

ANATOMY OF INGUINAL HERNIA

DESCRIPTIONS of the surgical anatomy of the inguinal region usually assume that the arrangements of the structures met with at operation for hernia is the same as is found in dissection of the normal, non-herniated subject Ashley and Anson[2] have made careful dissections to decide how far this is true They found that indirect passage of a fairly large hernia did not take place—the peritoneal sac passed through the wall directly, in its course displacing the inferior epigastric artery inwards, so that the first part of the artery passed almost horizontally, and then turned at a right angle to pass upwards behind the rectus abdominis muscle Hesselbach's triangle did not exist The inferior epigastric vessels were thus important medial and inferior relations of the neck of the sac The sac had a more medial disposition than is conventionally described, and on the floor of the abdominal ostium was formed by the iliac vessels, the anomalous obturator (present in this case), the ductus deferens and the internal spermatic vessels Their other main observation was concerned with the identity of the various coverings of the hernial sac These are usually described as the external spermatic fascia, derived from the external oblique, the cremasteric fascia and muscle, derived from the internal oblique, and the internal spermatic fascia, derived from the transversalis muscle By dissection the coverings were identified and separated in the scrotum and traced upwards to the parietal layers of the abdominal wall It was found that they could be definitely followed to their source In all cases examined the contribution from the external oblique was entirely fascial, consisting of the conjoined fascia which invests the two aspects of the muscle In the cremasteric layer scattered muscle fibres were identifiable, but there were no definite aponeurotic fibres, and it was concluded that this layer was predominately fascial The internal spermatic covering represented a fusion of the thin outer lamina of the fascia investing the transversalis and iliopsoas muscles and the thicker inner one, commonly known as the transversalis fascia

MR E Rock Carling, senior surgeon to the Westminster Hospital, and Dr S P Bedson, F R S, professor of bacteriology in the University of London at the London Hospital, have been appointed members of the Medical Research Council, in succession to Prof G E Gask and Dr W W C Topley, F R S, who retire on Sept 30

MEDICAL SERVICE FOR THE HOME GUARD *

G B Shirlaw, L R C P.E
ASSISTANT MEDICAL OFFICER (A R.P) FOR BATTERSEA

Provision of a medical service for Home Guard detachments serving in urban areas is not a question of devising new means but of using those which exist already. It has now been officially announced that doctors can be enrolled in the force. Health problems will not normally be considerable, for the men will be covered by national health insurance. A close watch should be kept on older men, who may develop ailments resulting from overstrain, and guard duty involving long hours on their feet may mean foot troubles for the sedentary workers, but during the period of waiting the chief duty of the doctor in charge will be planning his casualty service for when trouble starts.

THE COAST TOWN

The Home Guard M O. and his colleagues will work directly under the local command, and in close contact with the heads of both civil and military medical services. If a town is of great strategic importance—on the coast, for instance, and in the obvious path of the invader—it may be assumed that in a serious attack the military authorities will take over everything, evacuating as far as possible the civilian population, or at least sending it to shelter when battle is imminent. The military will probably use existing stations which the civil-defence organisations have established—first-aid posts, ambulance depots and decontamination plants—and they will certainly make use of any hospitals sufficiently removed from the main zone of battle which are still functioning. The Home Guard doctor will find himself part of a well thought out system.

If this complete absorption of the civilian casualty services takes place there will be some obvious difficulties. As an example, there are two patterns of stretcher in use in this country—Army and A R P. They fit two different types of ambulance and are not interchangeable. Few things are worse for a casualty than shifting from one stretcher to another. Wounds are reopened, pain is restarted, fractures are jarred, shock, which may be passing off, is suddenly intensified by hurried and unexpected handling. It is the aim of casualty organisation to reduce such disturbance to a minimum. The Home Guard doctor who has foreseen this difficulty and has made plans to avoid it—either by careful ear-marking of ambulances or some device (if that is possible) producing interchangeability—will have done a good service to his area.

If the military take charge of a coast zone it by no means follows that the Home Guard will be absorbed completely. The type of situation most likely to arise is a shore battle area under absolute military control, and lines of communication guarded at frequent intervals by bodies of local volunteers. These lines will be under continuous bombardment from the air and there will be a fair number of casualties. Civilians nearby will also suffer, and the normal A R P. services will deal both with them and with any injured members of the Home Guard. But suppose the first attack is held. If the area has been badly strafed advantage will be taken of the first respite to get civilians back out of danger. Special routes may be allotted to them so that military needs are not encumbered and the Home Guard may conceivably have the task of shepherding the refugees. Once this is done the guardsmen will return to their defence duties, but now they may be working in an area from which civil casualty services have been evacuated. The Army will have its hands full. The Home Guard doctor who has not planned in advance for this emergency will have to improvise his own medical service under very adverse conditions. If the whole subject has been considered during the training period and proper liaison established with the military and A.R P authorities no hiatus will occur. Certain civil defence units will remain to serve the H G posts along the communications, or the R A M C may have the situation in hand.

THE INLAND TOWN

In the large inland city an entirely different problem exists. It is in the highest degree unlikely that the enemy advance having established shore bases will be able to attack industrial cities en masse, if such a break through occurs it will appear for the moment almost invincible yet will in reality be of astonishing vulnerability. Invasion attacks, however they spread their branches, suffer from a serious root weakness. Already naval reinforcements may be striking a shrewd blow which will smash the source from which the attackers' strength is drawn. Soon the snared battalions will advance not from choice but only because all possibility of retreat is denied them. This point of strategy should be made widely known.

Granted the unlikelihood of such attacks developing the duties of the Home Guard M O in inland towns of any size will best be carried out in conjunction with the A R P authorities. Large numbers of regular troops, bringing with them the R A M C, are not likely to be stationed in cities like Birmingham and Manchester. Attack upon such centres will be by air bombardment and by parachutists. The Home Guard will have to withstand the one menace and rapidly finish off the other. If air attack is so severe that the city is devastated, then the military may have to be called in to aid the civil defences. Fire-fighting, care of wounded, maintenance of essential supplies and the preservation of morale might in the last resort require the presence of the Regular Army, but the soldiers would not come in large numbers and would leave as soon as their work was done. Assuming that attacks on large towns take place on the lines here indicated, the Home Guard M O will probably have to rely entirely on the coöperation of the civil defences.

In the town as in the country the main functions of the Home Guard are static. The essence of a casualty service is, on the other hand, mobility. Casualties have to be evacuated, the local volunteer force must always, at all costs, stand firm. The Home Guard will sometimes be acting as besiegers and sometimes besieged. From the point of view of the H G medical officer the handling of casualties can be thought of in terms of these two phases of action. Either phase may at short notice develop into the other. Evacuation of casualties may take place in three ways —

(*a*) Siege evacuation—the withdrawal of wounded to some safer central point in a building or area which the enemy have surrounded.

(*b*) Local evacuation—the removal of casualties to safety from a fluctuating line of strong points or barricades.

(*c*) Total evacuation—the withdrawal of wounded from an area made completely untenable from the casualty point of view.

When the H G defences of a factory are planned as a unit some point must be set aside as an aid-post. It should be as bomb-proof as possible and self-contained in equipment. Electric water heaters, for example, are not much use when an enemy has cut the cable, nor is a brightly polished tap of value when the water has ceased to flow. Each Home Guard section must have what in the Regular Army would be termed its regimental aid-post and when this is near an objective likely to be bombed it must have corresponding protection. A few sandbags and a piece of board nailed across a window are not enough. In cities the aid-post should be underground and beneath as many floors as possible of reinforced concrete. Such places are reasonably common and usually part of them can well be spared for casualty service work. All underground posts should be as big as possible even if the equipment provided is not in proportion to their size. In a heavily bombed town the hospitals might become either overcrowded or unusable and damage to communications might make the working of official evacuation schemes very difficult. Equipment salvaged from damaged hospitals can be quickly installed in underground aid-posts if space is available and if the posts are of sufficient capacity large numbers of wounded can be tended till evacuation conditions improve.

---

* Abridged from a chapter of "Medicine v Invasion," by G B Shirlaw and Clifford Troke, shortly to be published by Messrs. Secker and Warburg

While planning cooperation with the civil-defence authorities the Home Guard M O must aim at a fair level of medical self-sufficiency in units under his care While in the large underground aid-post there will almost certainly be an adequate number of A R P first-aiders, in the smaller H G regimental aid-posts there will only rarely be such assistance available It is essential, therefore, that at least two men in every detachment shall have reached a dependable standard of first-aid So far the medical supplies issued to the H G have been on a very small scale, but as the supply position improves proper battalion stores will obviously be accumulated, for there seems no valid reason why the level of equipment should in medical respects fall below that of the regulars Both sets of men run the same risks

The M O should have under him at least a sergeant and corporal for the control of a sufficient number of stretcher bearers These men must be trained not only in first-aid from a strictly common-sense military point of view, but also in the technique of casualty collection under fire In the best of the men this will be instinctive, but a good deal can be taught Collection of wounded is not always possible and must never be attempted when likely to restrict the fire of a strong point under pressure Normally, men who are injured in an isolated pill-box will have to remain till the whole situation is dealt with and the enemy are either rounded up or in full retreat When, however, a pill-box abuts on buildings whose approaches are commanded by other strong points and entry to which can be made without undue hindrance to supporting zones of fire, it should be possible to get the wounded clear without disproportionate danger It may even be possible to move up an ambulance under the shelter of a friendly wall

The town casualty service depends finally on the hospitals These are difficult to defend, they have large expanses of glass, few strong points and numerous approaches, while the presence of wounded within them adds greatly to the defenders' problems Once they are isolated and are being defended from inside their usefulness to the main forces in the town is ended—they can receive further casualties only from the ranks of their defenders The aim must be to keep them as part of the main defensive system within the town, thinking of them not as single buildings but as centres with communication lines

From any defended point the lines of evacuation run to hospital or aid-post It is essential to have more than one line In trench warfare it is known with certainty from which direction the attack will come, but in the type of conflict which we shall be facing this can rarely be known An ambulance going to a single pre-arranged collection point in the rear of a strongly defended post may find that it is from the rear that the attack has come and blunder straight into the attackers Each fortified post or system should therefore have several known collection points—A, B, C, and D they might be called—so arranged that casualties can always be sent to the point which is farthest from the main attacking thrust In giving instructions to the ambulance the A R P Control Centre will not say " collect casualties from West Station " Directions given will be more precise " West Station attacked from the north along main line Remove casualties from collection point B " Reference to the appropriate map shows that point B is a cellar in a goods yard to the south of the station

Such improvisations as these will spring to the mind of any M O who studies his job in advance, but they are the bravura passages The main body of the advance work will consist in the laborious collection of information from a dozen different sources, the creation of smooth liaison with military and civil authorities who may display inertia if not displeasure when confronted by Home Guard keenness, and the training in rational first-aid of well-meaning men who at their worst will appear to the doctor as homicidal maniacs Perseverance and clear thinking will solve all problems of information, liaison and instruction The Home Guard M O must start out on his job determined to obtain first a clear-cut picture of the civilian and military administration of his area secondly, plain undertakings from the authorities concerned as to what help will be available to him and under what conditions, lastly, a level of casualty drill on the part of the men in his charge which will ensure that no life is lost through ignorance or inefficiency.

RURAL AREAS

The task of the Home Guard M O in the prosperous country district, where villages are numerous and there are a few fair-sized towns, involves certain basic difficulties These are distance, the scarcity of doctors, and the absence of proper A R P sense in the average village A village which in the terror raids of last autumn, and in the dislocation raids of the present time, has meant nothing in the Nazi scheme, may become a target of the utmost importance in an invasion Since the defence does not know the invasion plan the pivotal nature of a particular place may not be obvious till the attack has begun, so a village hitherto undisturbed may find itself suddenly a target for dive-bombers and with no anti-aircraft batteries available The attack may have no military objective in the strict sense of that term, and may be intended only to set the villagers in flight, causing them to block the roads The first task of the Home Guard M O in the well-peopled countryside is to show villagers their importance in the scheme of things

The A R P service in a large village is usually no more than a first-aid point a small room with a first-aid kit of about the same size and usefulness as the contents of the average pouch The room may be a disused toolshed, the kit will vary in completeness Its contents may have been drawn on in civil emergencies, not excluding veterinary surgery On the other hand there may be found in a small village a level of intelligent preparation which would shame some towns Rural aid-posts are a mixed bag On them, however, the Home Guard must rely when casualties are incurred, and the first duty of the M O is to make a personal tour of inspection as tactfully as possible It is unwise to depend on statistics in the files of the county medical officer unless you are sure of his quality He may be a brilliant organiser, full of ideas for research and progressive treatments, or he may be a delightful old fellow who has taken a country job because it permits all the pleasures of retirement at a salary usually associated with the performance of useful work

The Home Guard M O must next enrol as many nurses and doctors as he can muster From these he must exact the promise that in case of trouble each of them will proceed to a given point prepared to meet a certain need As this process of enrolment goes on it will almost certainly become plain that the supply of doctors and nurses is inadequate and that a complete fusion of A R P with the Home Guard is needed from the medical point of view The main difficulty which will be encountered in any scheme of fusion is control Though we are all loath to resign authority, it is essential that no doubt shall exist in a military organisation as to who has ultimate control The pitfalls of dual command are obvious and must be avoided from the start If the county medical officer in conjunction with the local M O H is willing and able to undertake the medical organisation of the Home Guard the question of twofold authority will not arise Once an understanding of this nature is arrived at the path to efficiency is smoothed The county may be a convenient area from which to plan, on the other hand, some other regional system may be preferable, but whatever area is taken it must be divided into sectors and medical control for a time of emergency established in each

Lines of casualty evacuation corresponding to various possible situations will have to be laid down Evacuation falls under one of three heads (*a*) siege, (*b*) local, (*c*) total In other words, if a village is attacked casualties may be carried (*a*) into it, (*b*) to a nearby village, or (*c*) out of the whole area The phrase " total evacuation " is here used only in relation to the wounded, and does not mean that everyone is cleared out of an area Total evacuation is an ideal policy, and like most ideals has little hope of being realised In any event it will usually have to be postponed till the scope of the whole conflict is apparent In dealing with siege as distinct from local evacuation, however, various interesting questions are raised immediately The advantages of siege evacuation are that it is rapid and that the conditions likely to be met with are known The disadvantages, which are equally obvious, may be summarised as follows

1 The presence of wounded in a surrounded post hampers the defenders and may lower morale But it must be pointed out that if a post is surrounded the wounded are bound to remain in it, and that men may fight all the better knowing they are protecting their injured comrades

2 The point when surrounded may be bombed from the air This means additional risk for the wounded. But where in total war will they be immune from such risks ?

3 Skilled medical and nursing help, by remaining in an endangered position, risk capture along with the wounded, and cannot well be spared This risk can in part be provided against by issuing clear instructions to skilled staff as to what their duties are A doctor must always remember that his responsibilities are to the many rather than to the few, and he must be prepared to risk the charge of cowardice from the uninformed if quick retreat means the continuance of his service and courageous delay may involve its total loss

Local evacuation has similar advantages and dangers The transport situation may be difficult, the roads long and bad ; there is always in parachute warfare the possibility of enemy being encountered in most unlikely places To offset these considerations is the fact that the underlying principle of good casualty work is always to get the wounded away as rapidly as possible Further the possible immobilisation of medical staff with valuable equipment is a risk which must be avoided as far as human foresight can provide against it The problem will be modified by local conditions but when the enemy attack comes from one definite direction and the defence is falling back, casualties should be evacuated to the nearest village behind the defensive positions A state of siege may after all, be avoided, and even if it is not there is no certainty of capture Relief should always be speedy reinforcement is far easier for the defenders than for the invading enemy Even if wounded and medical staff are captured they are not a certain loss Swift recapture of the position is possible, even likely.

THE VILLAGE AID-POINT

Accessibility, safe structure and good equipment should be aimed at in a village first-aid point Stretchers should be provided, with efficient stretcher-bearers, and a reasonable number of vehicles should be earmarked for the collection of wounded The medical man assigned to the post should be thoroughly acquainted with its staff and equipment Rehearsal is the best means of ensuring smooth working, but it is useless if not thorough, since faults do not appear and false confidence is bred The post should be centrally placed to enable it to be easily defended A centre may be mathematical, geographical, or strategic , the village F.A.P. need not necessarily be at any one of these The strong points on the village perimeter will probably be bombed , so will the social focus of the village as observed from the air. for it will be here that the headquarters will be presumed to lie The F.A.P. can best be placed in the intervening region provided it is sufficiently central to be in comparatively little danger of capture A military casualty clearing station must be sited not only for ease of collection of cases but also with a view to ease of clearance Evacuation routes must not however. be those of great military importance In the first place every convoy of wounded occupies space valuable to advancing reserves , in the second any main route or road junction is a certain target for the bomber and the fighter, suddenly aware of a chance for machine-gun attack. The leafy lanes sometimes sunken which are found in so many parts of England, will often afford an ideal means of bringing ambulances well up to the zone of battle The needs of aid-post regimental station field-ambulance centre, and casualty clearing hospital are alike in this—each demands strategic placing in relation to road, rail or river, sound camouflage adequate protection and a high degree of mobility With regard to camouflage it should be observed that hospitals, however well concealed their buildings or tents may be will inevitably reveal their position if all their washing is hung to dry in the sun, or if a stream of ambulances one after the other, raise characteristic dust-clouds along a road Nurses will do well to conceal their white uniforms when sent out on mobile hospital work They can be seen for miles on a clear day, and should be covered by a khaki macintosh

Unless the number of wounded is large, the trained staff should not leave the village , but if casualties are considerable at some distance it may be urgently desirable to send reinforcements to the place For this purpose small well-protected convoys must be formed consisting in their simplest form of a car and an ambulance In this way additional collection bases may be set up where needed and the cases classified as urgent or non-urgent on the spot The disposal of urgent cases depends on what hospital facilities are available The nearest town to possess adequate surgical necessities may be situated too far away, in which case surgical teams must be summoned to meet the serious cases at a convenient rendezvous Communications are likely to be a serious problem The telephone may not function reliably. but when it fails cyclists can be called upon The wardens' service will have worked out systems of communication and these should be, in general available to the Home Guard

Though each aid-post should have means of becoming mobile in a special emergency the central area under the orders of a chief medical officer should endeavour to have several mobile units in reserve These should be sent forward if a serious casualty situation appeared likely to develop on any section of the front, and they should aim at forming either an advance dressing post or a main treatment and classification post as required Camouflage is important for such purposes It is no use the Home Guard becoming expert at concealing their whereabouts if their ambulance units are to betray them Training must be thorough, and if skilled tuition is not readily forthcoming a good officer must get what literature he can and work things out for himself If a few simple textbook principles of a technical nature (and so not likely to be arrived at by common sense alone) are firmly grasped it is amazing what the comparatively unskilled unit can accomplish

Speedy evacuation must include practice in the quick getaway under conditions of surprise attack An exercise in which this is accomplished under cover of a defensive action by a special H G force should prove of great interest to members of the section Large-scale tests of this type are so difficult to organise that field tests tend in some quarters to be neglected This is a mistake , an extensive exercise of a volunteer force is awkward, for men have their livings to earn and the time they can spare is limited but much can be learned by a series of small affairs Their subsequent dovetailing in theory will provide excellent lecture material

Difficult though A.R P. work may be under blitz conditions, it is simplicity itself compared with the casualty problems which arise when the Home Guard are pictured at grips with invaders In air-raid casualty work the medical officer's responsibility is largely towards individuals By his good work they are saved by his errors or neglect they die. But faced with the task of sustaining morale in small groups of men who may be forced to fight to the death against considerable odds the M O may feel that the responsibility is beyond his powers Not individual but national survival is threatened He may well pray for complete military intervention to relieve him from the burden of decisions fraught with danger If there is one quality. however, which by the nature of his position the country doctor must possess, it is self-reliance No-one who knows this body of men will doubt their steadfastness in time of trial

---

AGE-LIMIT FOR OFFICERS OF IRISH LOCAL AUTHORITIES

By a bill which lately passed both houses of the Oireachtas a radical change has been made in the tenure of employment of all officers of Irish local authorities including of course the medical officers generally known as dispensary doctors who make up nearly a third of the entire medical profession in Ireland Hitherto, these officers when once appointed held office for life and could only be removed for misconduct or because they had become incapable of performing their duties by reason of infirmity of mind or body or because their office had been abolished By the new legislation the minister for local government and public health will be empowered to declare an age of retirement for each class of local officer, which will become effective six months after it is made The minister will have power to fix different ages for different classes of officer

The bill passed through the Dail without criticism of this point, but an amendment was moved in the Senate that the section should not apply to part-time officers whose terms of appointment included no compulsory retiring age It was pointed out that the clause interfered with an existing contract between the medical officers on the one hand and the local authorities and the department of local government on the other , that the expectation of a tenure of office uncontrolled by an artificial age-limit attracted candidates to the service , and that adequate powers were already in the hands of the minister to compel the retirement of an officer rendered by age incapable of performing his duties The amendment was rejected by the minister, who maintained that a fixed retiring age was necessary, since at present he found difficulty in securing the retirement of elderly officers He emphasised that it would be open to him to fix different ages for different classes, and he expressed the opinion that 65 would be unsuitable This admission was welcomed, for it was remembered that some five years ago the department had circularised local authorities advising them that 65 should be made a compulsory retiring age for all their officers The circular was phrased so as to appear mandatory on the local authorities, and was acted upon in some instances The Irish Medical Union, however, challenged the circular on legal grounds, and the department had to admit that it had no powers in the matter and that the circular was merely advisory It had been feared that if an age-limit was fixed it would be at 65

In England Now

A Running Commentary by Peripatetic Correspondents

I AM concerned about the V campaign Up to date it has reminded me of an Oxford don in a writing-on-the-lavatory-wall competition I don't want to be censorious, but a Government, eighty per cent of whom were guilty of the gross psychological error of appeasement, the zoological equivalent of which is trying to stop a pack of wolves with a bag of monkey nuts, mustn't be offended if we professional psychologists offer advice I feel that Quentin Reynolds and "Cassandra" were on the right tack when they held their opponents up to scorn on account of their Christian and surnames At first it may seem rather strange that Hitler, who is responsible for millions of blasted lives, a lake of children's blood, sorrow that will rake for fifty years, a thousand tides of terror, a holocaust of youth, a pyre of pain, should be jeered at for having a Christian name that he couldn't help, and for changing his surname from Schickelgruber to Hitler, which seems rather sensible But that's not the point The point is that war is a reversion to a twelve-year-old state and this is the authentic twelve-year-old touch Now, Colonel John Bull Britain (oh how withering !), let's see whom you have on your committee What, Lady Pouncey ? O tut ! Lord Agar ? Pshaw ! I'll have to choose them for you You, Smith minor you who organised your class to stare at your new form-master's fly-buttons until he blushed, I know you got six of the best for it, but your country needs your genius now my boy Come along And that girl of G A Birmingham's who worked in a small Irish hotel and wanted to get rid of the guests, so all their food tasted of paraffin, even the boiled eggs which she contrived with a hat-pin You need girls like that, Colonel B Wire for her at once at Ballyshannon She'll command our Ninth (Cranial) Army Corps Now for the Eighth You, Jones minimus, who ever drum on desks, whistle just out of tune kick tin cans, tattoo on iron railings, specialise in slate-pencil noises, make succulent sounds which I am creditably informed by the bootboy are technically known as "raspberries," you're the man for this Do you know the dog whistle, J minimus, which will bring a dog to heel, but is inaudible to man ? Well, we'll show you how to make one which will keep the Hun's ear on edge They with their dive bombers and whistling bombs have used that pathway down the chorda tympani to rack the parasympathetic so will we I need not remind you, General Jones, that it is the ragged, irregular, very highly or very lowly pitched, unmetrical noises that are particularly trying, especially at bedtime and very early morning And you, young Robinson, who got soundly beaten for making mercaptan in the laboratory, we humbly apologise, we need your enterprise now You shall command our First Army Corps And you, all you other little swine, who carry caterpillars in match-boxes and keep mice in your desks, we need you too We'll give you grisly things to do with tænia eggs and jolly acari We'll train an army in the mystery of making "Russian fleas" —finely chopped horsehair, steeped in an irritant, which tactfully placed on chairs will work through Prussian breeches and even irritate barbarian skin What's that you say, Colonel B ? Childish and beastly Yes, I know, but then war is a very childish business in spite of its mechanisation, and when it comes to man being dominated by brutes, then unarmed man seeks his ancient weapons Onward pin-prick soldiers

* * *

The disruption of family life leaving me with more evening leisure than was pleasant, I decided that it could be used most profitably for the war effort in first aid instruction So for the past two years I have done a good deal of lecturing for the St John and other bodies, and have spent even more time in examining first-aid candidates In the course of all these examinations of both elementary and advanced first-aiders I have not met a single candidate who had any conception of what shock was They all knew the treatment, nearly all knew the signs and symptoms (or most of these) but they had no real understanding of why they occurred Nor was there a single candidate who knew that shock might make its first appearance eight hours after an injury One should not, of course, expect detailed and scientific knowledge in first-aiders, but I have always found classes respond much better when they are told Why as well as How I devised the following model to link the symptoms of shock together, and to correlate them with hæmorrhage

"Let us imagine that this building is heated by a closed hot water system which has a fire to heat the water, a pump to drive it round the pipes and a cistern which is *normally* half full Now the room gets cold and we go to find out why The fire may have died down, the pump may be faulty, the pipes may be leaking, or the cistern may have filled up completely With the exception of the first case the volume of circulating water is reduced and so less heat is carried round the building Now let us relate this to the body The fire corresponds to the chemical processes of the human organism and these may be damped down by disease and long exposure to cold and strain The pump is the heart, and when it fails we have collapse (sometimes associated with the failure of the 'fires') If the pipes have burst and water is pouring down the outside of the building, that is the same as external hæmorrhage—you can see the bleeding without difficulty But the pipes may have burst in such a way that the water is running into the basement, and is not easily spotted because none appears on the outside This is the same as internal hæmorrhage Finally, the whole system of pipes may become porous so that water escapes in small amounts all along their course and at the same time the cistern fills up completely This is the picture of shock In this condition, for reasons which are not well understood, the blood-vessels allow some of the blood fluid to pass through the walls, thus reducing the amount of circulating blood , in addition, blood tends to stagnate in the liver, spleen and large abdominal veins (This is a rather controversial point but the lecture is for first aiders, not experimental pathologists) The essential thing is that the volume of the circulating blood is reduced

"Now I have already told you that one of the chief functions of the blood is to carry oxygen round the body If the amount of oxygen is reduced every organ will be affected The brain does not work so well, the patient therefore becomes anxious, confused, stuporous and finally comatose The muscles do not get enough oxygen so that they cannot contract so well, and the patient becomes weak The lungs try to make up the deficiency and breathing becomes laboured The heart receives messages to counteract the trouble, and beats more rapidly in an attempt to drive the smaller amount of blood round the body quicker So the pulse rate goes up But the heart does not have enough time to fill, and its muscle is not receiving sufficient oxygen so the beats are weaker The normal amount of blood is not flowing through the skin, and what there is is darker in colour, so the patient assumes a leaden pallor As the amount of oxygen carried round the body is reduced so the intensity of chemical actions is lessened and the body temperature falls All these things occur in external and internal hæmorrhage and collapse and shock. From this you can see why we treat these cases as we do You will see also that if you remember the fundamental fact that the blood-volume is reduced in these conditions, then you can easily work out for yourselves how all the signs and symptoms are produced '

This model will perhaps not bear searching analysis from the physiological or pathological viewpoints It does however pass the pragmatic test and satisfies the student's curiosity

Most of us I hope would agree with your peripatetic philosopher when he says that our national system of education requires a complete overhaul after the war It is only at the point where we must decide in what ways we propose to alter it that our views begin to diverge Despite the now thoroughly stale gibes at the public schools I for one think that with all their faults they represent the best kind of education we have to offer. We have been told ad nauseam that the competitive type of education they provide with its accent on athleticism makes for war-mindedness but does it? Some nations with nothing approaching a public-school system of education have done a good deal of fighting in their time and we ourselves had a war or two before the public schools really got into their stride. Can the few public schools then extant be held responsible for the doubtless regrettable if highly successful, pugnacity of the Elizabethans? I doubt it The cry that public schools breed class-consciousness is of course, only half true; the real cause is the dual system of education which engenders a feeling of inferiority in those who consider that they have been given something less than the best available Indeed the most socially uncomfortable and class-conscious persons one meets are those who have been educated at secondary schools and subsequently graduated at a university For some reason they are apt to be perpetually on guard and to view the lightest and most innocent conversational opening with suspicion

By all means let us have a single system of education equally available to all children irrespective of the size of the parental purse but let it be built on a high and expanding level of excellence If we contrived to make our improved and ever-improving public schools really public we should have done something worth while. Turning to medical education it seems reasonably certain that come what may something akin to the present general practitioner (only better) will be required in considerable numbers and I would suggest that the present curriculum be drastically revised to meet the basic needs of general practice. First I would have students taught to read, write and speak their own and at least one other language before embarking on the study of any technical aspect of medicine All preclinical studies might, I think, with advantage be curtailed, it is not in the laboratory or the lecture theatre but in the wards and the outpatient departments that the student will learn most of the things that will be useful to his future patients For the embryo general practitioner to stand for hours in the theatre watching major operations that he will never be called on to perform is a pure waste of his time On the other hand, let him administer all the anæsthetics he can, do all the minor surgery he can see and learn to diagnose all the surgical emergencies he can see all the acute and chronic medical cases he can and learn far more pharmacology and therapeutics than he does at present I would have him taught prognosis by an experienced general practitioner and he should do a course of practical domiciliary nursing As for midwifery I would allow none to practise it until he had had at least six months' postgraduate experience at a maternity hospital or, better still assisted at, say 50 cases delivered in their own homes by experienced general practitioners Lastly, before letting him loose on the public I would have him either travel round the world as a ship's surgeon or else tour that dreadful Europe meeting and mixing with all sorts and so overcoming his prejudices for the general practitioner must look on his patients as individuals unique phenomena in nature not to be liked or disliked because they fit in or fail to fit in with his own peculiar code of ethics or standards of behaviour

Recently I renewed acquaintance with Ern and Jim those skilled agriculturists, whose roots are so deeply embedded in the soil that they pay no heed to " this trifle war " Being pressed by a humane master to take a well-earned holiday on full pay they consented but with considerable reluctance. Ern went first, was thoroughly bored and miserable and returned to work before his leave had expired Jim no less unskilled in the art of leisure so beloved of intellectuals, gravitated to the pub and solemnly filled himself to the brim and overflowing with cider. The local policeman kindly gave him a lift home in a car and on being helped out Jim returned thanks by saying: " You'm ony a p liceman and got no manner o' right on our place, git orf! ' The menacing gesture that accompanied these powerful words would, I understand have been more impressive had Jim been less whistled and so able to stand poised instead of staggering in all directions Next day I met him full of alcoholic remorse. He had sneaked back to the farm while the rest of them were dung-spreading and was furtively carrying a bucket of water to the goats and " giving an eye '—as he described it—to the sheep " If you re supposed to be on holiday Jim " I protested, " why do you come back to work? ' He shifted uneasily and shook his head. " Allus plenty to do on a farm, doctor ' he said

* * *

Adventures like misfortunes, seldom come singly One afternoon I was summoned by a dentist to administer gas to an immense and powerful man who confessed that he was nervous of anæsthetics While he was going under he began to box and from my point of vantage behind the stumps it was pretty to watch his footwork. He kept putting out a nice straight left at the nurse who ducked and side-stepped neatly and at intervals he swung a wicked right dangerously close to the dentist s jaw. We got him down at last and having pinioned his arms securely with a couple of towels the dentist was able to draw the offending teeth " How many rounds did I go ?' was the patient's first question on regaining consciousness " The last time I went to a dentist ' he added dreamily. " I knocked the poor chap out " It turned out that he had been a prize-fighter and has since become a theological student - an instance of muscular christianity That same evening I was called to see a cow. Jim and Ern met me with long faces. " Er s dyin' on 'er feet " said the pessimistic Jim " and there s nought as you can do for 'er ' Where cows are concerned we have only two diagnoses—if they are ' blawed we call it " the information," and if they are breathing fast 'tis the pewmonia This one was certainly very ill with pyrexia, a staring coat and tachypnœa, so we diagnosed pewmonia. I dissolved 10 tablets of sulphapyridine and injected the solution into the buttock. Much to everyone s surprise she was still alive next day so we injected some more sulphapyridine Next morning she was obviously moribund and had to be shot It was just bad luck that the postmortem carried out at the local abattoir revealed that she had swallowed a piece of wire which had touched her heart As her owner observed, we had the satisfaction of knowing that we had done all that modern science could do and her relations could have no cause for complaint.

* * *

When I passed the kitchen door on my way to breakfast this morning a gloomy voice was remarking " One breast-fed baby, remember, dies for every five fed in other ways " Shades of William Farr! Think of the feelings of a mother who has just had to give up feeding her baby on the breast for some very good reason when handed this kind of remark sandwiched between recipes for cooking carrots Of course she might ring up the B B C and ask how many breast-fed and how many bottle-fed babies there are but if she isn t a born fallacy-spotter she may just brood

Letters to the Editor

STANDARDISATION OF DIPHTHERIA PROPHYLACTICS

SIR,—Your leader of Aug 9 is opportune, but I fear it does little to achieve what it very properly advocates—a standard method and technique Let us be clear on this subject The following statements are well documented, as anyone may verify by consulting the literature, which, incidentally, has been reviewed in my monograph on the subject

1 The Schick test is for practical purposes a sound and certainly the most convenient test of susceptibility to clinical diphtheria The Schick-negative rate produced by any antigen or method is a good reflexion of the efficacy of that method but it is impossible to guarantee that any one Schick-negative child will not take diphtheria Furthermore, no small experience is necessary for the accurate performance and interpretation of Schick tests

2 The antigenic results produced by different preparations have not been consistent This is due to three main causes—differences in the original immunity and potential immunisability of a community, and in the antigenicity of the prophylactics used Two small well spaced injections of a reputable brand of A P T have given a constant Schick negative rate of nearly 98% I am unaware of any published work in this country or America where two properly spaced injections of A P T have given a low Schick-negative rate Undoubtedly the peculiar properties inherent in A P T tend to counteract any possible variation in antigenic power

3 If propaganda is to be effective it is essential that the parents and the child be caused as little inconvenience as is possible, every effort should be made to limit the number of injections necessary

These then are the facts How are they to be applied ? Few will deny that A P T is the preparation of choice for general purposes, for it is more effective in two doses than the others are in three But in using A P T, as any other preparation, it is necessary to guard against possible variation in antigenicity and this can be done in two ways—by Schick testing all cases after treatment, or by studying the effect of increased dosage

The Schick-testing of all cases is inadvisable for the following reasons

The test is not infallible and so in individual cases one cannot guarantee immunity Experience in performance and interpretation of the test is necessary At the present time large numbers of doctors have been called on to carry out immunisation who through no fault of their own do not possess this experience It would be as unreasonable to expect inexperienced people to refract a mixed astigmatism or to remove an appendix as to carry out a Schick test

A Schick test means two extra visits for parent and doctor, this will seriously hamper the work of effective propaganda It will cause extra expenditure of time and material and no guarantee of absolute immunity can even then be given

After A P T if further measures are thought necessary it is more logical to give a third injection of prophylactic

As the routine use of the Schick test is untenable attention must be given to dosage and technique in administration of the antigen There are sound reasons for thinking that the dosage given below will give a very high degree of protection and will allow for possible variations in antigenic power due to environmental conditions or due to different batches of A P T The method is as follows

In children under eight years 0 5 c cm of A P T intramuscularly into the extensor aspect of the left arm Interval at least a month and a similar dose repeated into the right arm

In children over eight, 0 1–0 25 c cm of A P T intramuscularly into extensor aspect of left arm Interval at least a month If no reaction to the first dose, 0 5 c cm intramuscularly into extensor aspect of right arm

No final Schick test to be performed

There remains the possibility that a very poor batch of A P T may inadvertently be issued for general use, an unfortunate happening that some think has taken place recently How can this be prevented ? The methods of manufacture, reagents used etc, should be laid down and manufacturers should adhere strictly to the procedure Some of the provisions of the Therapeutic Substances Act may require revision or qualification In addition, arrangements should be made for any new batch of A P T to be tested on a small group of children This should be entrusted to a worker with wide experience of Schick testing and should be carried out in an area where the diphtheria incidence is fairly constant and on children of the same age and social status (This, of course, is a very different matter from general routine Schick testing of all cases)

These precautions would mean a preparation as nearly standardised as possible and tested before issue The larger dose would almost certainly suffice to counteract any variations in antigenic effect resulting from local environmental conditions (low latent immunisation and/or diminished immunisability) Your leader exhorts the Government—and this exhortation will be loudly echoed—to lay down a standard I submit that the above is the way to go about it

Croydon JOHN TUDOR LEWIS

CARE FOR HOME GUARD CASUALTIES

SIR,—Intimate personal experience of the great Jamaican earthquake, the last war, and fierce communal riots in Bombay, Calcutta and Johannesburg, where all medical communication by road or telephone was cut off for days, impels me, as the medical officer of a Home Guard battalion, to elaborate and criticise the leading article of Aug 16

When, and if, the balloon does go up, it must be fully appreciated that the Home Guard at "action stations" cannot depend upon the ready and efficient medical aid of A R P posts, for these are immobile and likely to be tried to the utmost by civilian incidents in the neighbourhood Moreover, it may not be even possible to reach or communicate with this organisation until after dark or until the roads and skies are clear Therefore, it is imperative that every company of a mobile or static battalion should be capable of dealing with its own wounded, burned or gassed men to the extent of 25% of its full strength At present, seeing that there is no provision whatever of medical (drug) equipment, it is not difficult to visualise the ghastly medical mess and devastating loss of morale that must result if the Home Guard were engaged in countering an invasion, say, next week Surely something should be done quickly to rectify this lamentable state of affairs. Is it fair or reasonable to suggest that M O 's of battalions (often over 2000 strong) should go round with cap and bell asking for donations to purchase urgent medical necessities that it is the duty of the state to provide ? Are we in the stress of battle to expect company officers or N C O 's (for there is only one M O per scattered battalion) to depend (in answer to a scrawled demand) on the limited generosity and critical attitude of some capricious O C of an A R P post, an E M S unit, or a military hospital, who, jealous of his own meagre supplies would probably require the certificated quadruplicated authority of the A D M S or Ministry of Health before parting ? No sir, let us have done with charity and muddling through after fifteen months of growing pains

It is my opinion that every company of every battalion should be provided with the minimum requirements in easy portable form, for dealing with the risks of pain, sepsis, burns, tetanus and fractures The outfit, in addition to the queer collection of inadequate splints and bandages you refer to, would be in charge of the N C O of a stretcher party who would be responsible to the company officer and/or medical officer

Pain would require morphia in tablet form for oral use and ampoules for injection, if a syringe can be obtained

Sepsis Sulphanilamide in 5 gramme powders in Cellophane packets or 0 5 gramme tablets should be liberally stocked The former for use in wounds, the latter by mouth Indeed sulphanilamide would be a fitting addition to every new first field dressing

Burns—Vaselined gauze sterile in tins, or tannic or acriflavine jelly, can be readily carried in screw-top metal jars

Tetanus—In the event of fighting in this country, it is more than probable that the incidence of tetanus will be high Therefore, as immediate evacuation is unlikely, antitetanic serum in ampoules or rubber topped bottles must be available, together with a syringe

Fractures—In every company there are men who have done a first aid course or obtained a certificate from the St John

Brigade It should not be difficult to teach these capable men the principles of plaster of-paris slabs or bandaging, thus conserving limbs and maybe lives, for we must all visualise conditions where it may be hours, and perhaps days, before casualties can be safely and properly evacuated

Although I have not touched on anti-gas equipment, I think you will agree that the supply of the suggested equipment to every company that may be working independently is urgently necessary if the medical department is to escape deservedly caustic criticism Stretcher bearers are not only beasts of burden—indeed, they demand that they be given the means, now denied them, of applying the knowledge they have acquired in their classes

I have calculated that the weight of a canvas-covered three-ply container, 18 in by 18 in by 8 in, fully stocked as above, including plaster-of-paris, for 25% of a company, would be about 14 lb

Harley Street, W 1 Y B Green-Armytage

VITAL STATISTICS WANTED

Sir,—No doubt your readers will have noted that a few weeks ago in reply to a question in the House of Commons, the Minister of Health gave the number of deaths from tuberculosis in England and Wales during the years 1939 and 1940 they will also remember how some weeks before that the Minister was reminded that there have been published no health statistics for these countries since those of 1938 and how he promised to try to make public a bare summary of the figures at some future date It may well be that there are sufficient reasons for this reticence, but it is a source of speculation and concern to those of us who are interested for we cannot help thinking how differently this matter is treated in Scotland For that country, Sir, the public-health statistics are available to us in summarised form quarterly with an analytical introduction to the report at the end of the fourth quarter This is admirable, but why is it not done in England? Why do we have to wait for a question in the House before we can discover that there has been a 7 5% rise in the tuberculosis mortality? It is in these particular figures that our interest lies, but statisticians and other workers interested in social health are wondering why the vital statistics and reports which form much of the raw material of their work are not made available, for without knowledge of the facts preventive action must be delayed

Edgware A S Hall

CALCIUM AND PHOSPHORUS STUDIES IN NORMAL PEOPLE

Sir,—Dr Robertson's paper of July 26 on this subject should be examined in detail, for our calcium requirements are much in the public mind

Calcium minimum —He found, as we did, that there is a "restricted" output under low calcium intake This suggests that some kind of conserving mechanism comes into action under a low intake Evidently the minimum figures in the various experiments depend to an important extent upon the amount of calcium the subject is in the habit of taking The real calcium minima are unknown and obviously lower than those given by the various investigators

Optimum calcium intake —I take it that by these figures Robertson means the calcium intake which completely saturates the subject with that substance (plus a quantity for marginal safety), so that he cannot absorb any more of it The question now arises What is the calcium level in the tissues of the experimental subject under an intake which just covers minimal requirement and a maximal (optimal) intake? Under the latter condition the reservoirs are full We were able to prove that the tissue calcium, too, in such circumstances is higher than under the minimal intake The crux of the whole question is, which of the two conditions is the more desirable? "Optimum requirement" in relation to what? Surely in relation to longevity or good health The vital problem is whether a calcium intake which just meets requirements, or which fills the reservoirs to overflowing, or one which is between the two points, is the ideal No data are available to judge which is the best Robertson's figure of optimal requirement is purely arbitrary—not supported by any evidence whatever Only long clinical observation can show which is the ideal We are confronted with a similar problem in regard to fat reservoirs Clinical experience has taught us that the average expectation of life of those who fill those reservoirs to full capacity is much below that of those who consume only sufficient to cover their needs Robertson does not realise that the calcium level in the tissues is different under a maximal (optimal) from that under a minimal intake He asserts that no harm can accrue under a large calcium intake since the surplus would leave the body via the fæces (This is not quite true part of the surplus is excreted by the kidney) The tissues contain more calcium under a large intake Whatever the action of calcium is, this obviously must be more pronounced under a high than under a low intake According to the textbooks, calcium contracts the vessels and raises the blood-pressure According to Jacoby (*Ther d Gegenw* 1916, 57, 161) calcium "thickens" the kidney filter and makes the performance of its function more difficult We found that the intravenous injection of 2 c cm of a 10% solution of Collosol Calcium (Harris and Levin, *J Physiol* 1937, 89, 153) definitely alters the character of the electrocardiogram, and we also drew attention to the increase of the work of the kidney under a larger calcium intake There is also a considerable amount of literature on the subject, including positive feeding experiments Clearly the assertion of Robertson that a large calcium intake can do no harm is quite untenable The requirement of calcium cannot be determined by experimental methods Clinically it is quite impossible for people to remain in a permanently negative calcium balance, without giving rise to manifestations It is strange that 15–20 million people should be suffering from a calcium insufficiency and not exhibit any signs of it The very rare condition of osteoporosis is now considered to be due to vitamin-D insufficiency

In our paper on calcium we did not refer to retention of the substance in the aged, I only mentioned it in a letter, based on an entirely different set of experiments We found retention of protein in the middle-aged, and we also found that wherever there was retention of protein, calcium too was retained ("High Blood Pressure," London) The reason is simply that part of the calcium is bound to the protein Robertson denies that there is retention of calcium in the middle-aged on the strength of figures given in table VI of his paper Now we pointed out in our paper that under a positive balance saturation must ultimately be reached, after which further absorption becomes impossible Obviously in the fully saturated cases the middle-aged cannot react differently from the young To demonstrate his point the subjects of Robertson's table should have been kept in a calcium-unsaturated state As his figures stand now they are irrelevant to the question of calcium retention in the aged

Why should Robertson think that as large a calcium intake as the body can possibly absorb, plus a margin of safety, makes for optimum health?

Liverpool I Harris

PHARMACY AND MEDICINES ACT

Sir —The concession in the Pharmacy and Medicines Act which perhaps attracted most attention and is regarded as the most satisfactory change in the law, is the clause requiring disclosure of composition of medicines Obviously its value depends on how far it fulfils its principal purpose—that the public should be fully informed of the nature of the medicines sold to them I submit that the two proposals of clause 6 provide safeguards likely to be illusory The reproduction of the accepted scientific name on the container has been widely adopted by the patent-medicine trade, which has not been slow in perceiving that this requirement gives the general public no information which they can appreciate Thus, a proprietary brand of aspirin declares that its product is "pure acetylsalicylic acid," a description which fails to inform the public that the product is nothing else than aspirin, which can be bought under that name at a fraction of the cost of the proprietary product The alternative afforded, namely the quotation of the description of the substance in the current edition of the B P or B P C, is equally ineffec-

Letters to the Editor

STANDARDISATION OF DIPHTHERIA PROPHYLACTICS

SIR,—Your leader of Aug 9 is opportune, but I fear it does little to achieve what it very properly advocates—a standard method and technique Let us be clear on this subject The following statements are well documented, as anyone may verify by consulting the literature, which, incidentally, has been reviewed in my monograph on the subject

1 The Schick test is for practical purposes a sound and certainly the most convenient test of susceptibility to clinical diphtheria The Schick-negative rate produced by any antigen or method is a good reflexion of the efficacy of that method but it is impossible to guarantee that any one Schick-negative child will not take diphtheria Furthermore, no small experience is necessary for the accurate performance and interpretation of Schick tests

2 The antigenic results produced by different preparations have not been consistent This is due to three main causes—differences in the original immunity and potential immunisability of a community, and in the antigenicity of the prophylactics used Two small well spaced injections of a reputable brand of A P T have given a constant Schick negative rate of nearly 98% I am unaware of any published work in this country or America where two properly spaced injections of A P T have given a low Schick negative rate Undoubtedly the peculiar properties inherent in A P T tend to counteract any possible variation in antigenic power

3 If propaganda is to be effective it is essential that the parents and the child be caused as little inconvenience as is possible , every effort should be made to limit the number of injections necessary

These then are the facts How are they to be applied ? Few will deny that A P T is the preparation of choice for general purposes, for it is more effective in two doses than the others are in three But in using A P T , as any other preparation, it is necessary to guard against possible variation in antigenicity and this can be done in two ways—by Schick testing all cases after treatment , or by studying the effect of increased dosage

The Schick-testing of all cases is inadvisable for the following reasons

The test is not infallible and so in individual cases one cannot guarantee immunity Experience in performance and interpretation of the test is necessary At the present time large numbers of doctors have been called on to carry out immunisation who through no fault of their own do not possess this experience It would be as unreasonable to expect inexperienced people to refract a mixed astigmatism or to remove an appendix as to carry out a Schick test

A Schick test means two extra visits for parent and doctor , this will seriously hamper the work of effective propaganda It will cause extra expenditure of time and material and no guarantee of absolute immunity can even then be given

After A P T if further measures are thought necessary it is more logical to give a third injection of prophylactic

As the routine use of the Schick test is untenable attention must be given to dosage and technique in administration of the antigen There are sound reasons for thinking that the dosage given below will give a very high degree of protection and will allow for possible variations in antigenic power due to environmental conditions or due to different batches of A P T The method is as follows

In children under eight years 0 5 c cm of A P T intramuscularly into the extensor aspect of the left arm Interval at least a month and a similar dose repeated into the right arm

In children over eight, 0 1–0 25 c cm of A P T intramuscularly into extensor aspect of left arm Interval at least a month If no reaction to the first dose, 0 5 c cm intramuscularly into extensor aspect of right arm

No final Schick test to be performed

There remains the possibility that a very poor batch of A P T may inadvertently be issued for general use, an unfortunate happening that some think has taken place recently How can this be prevented ? The methods of manufacture, reagents used etc , should be laid down and manufacturers should adhere strictly to the procedure Some of the provisions of the Therapeutic Substances Act may require revision or qualification In addition, arrangements should be made for any new batch of A P T to be tested on a small group of children This should be entrusted to a worker with wide experience of Schick testing and should be carried out in an area where the diphtheria incidence is fairly constant and on children of the same age and social status (This, of course, is a very different matter from general routine Schick testing of all cases)

These precautions would mean a preparation as nearly standardised as possible and tested before issue The larger dose would almost certainly suffice to counteract any variations in antigenic effect resulting from local environmental conditions (low latent immunisation and/or diminished immunisability) Your leader exhorts the Government—and this exhortation will be loudly echoed—to lay down a standard I submit that the above is the way to go about it

Croydon JOHN TUDOR LEWIS

CARE FOR HOME GUARD CASUALTIES

SIR,—Intimate personal experience of the great Jamaican earthquake, the last war, and fierce communal riots in Bombay, Calcutta and Johannesburg, where all medical communication by road or telephone was cut off for days, impels me, as the medical officer of a Home Guard battalion, to elaborate and criticise the leading article of Aug 16

When, and if, the balloon does go up, it must be fully appreciated that the Home Guard at " action stations " cannot depend upon the ready and efficient medical aid of A R P posts, for these are immobile and likely to be tried to the utmost by civilian incidents in the neighbourhood Moreover, it may not be even possible to reach or communicate with this organisation until after dark or until the roads and skies are clear Therefore, it is imperative that every company of a mobile or static battalion should be capable of dealing with its own wounded, burned or gassed men to the extent of 25% of its full strength At present, seeing that there is no provision whatever of medical (drug) equipment, it is not difficult to visualise the ghastly medical mess and devastating loss of morale that must result if the Home Guard were engaged in countering an invasion, say, next week Surely something should be done quickly to rectify this lamentable state of affairs Is it fair or reasonable to suggest that M O 's of battalions (often over 2000 strong) should go round with cap and bell asking for donations to purchase urgent medical necessities that it is the duty of the state to provide ? Are we in the stress of battle to expect company officers or N C O 's (for there is only one M O per scattered battalion) to depend (in answer to a scrawled demand) on the limited generosity and critical attitude of some capricious O C of an A R P post, an E M S unit, or a military hospital, who, jealous of his own meagre supplies would probably require the certificated quadruplicated authority of the A D M S or Ministry of Health before parting ? No sir, let us have done with charity and muddling through after fifteen months of growing pains

It is my opinion that every company of every battalion should be provided with the minimum requirements in easy portable form, for dealing with the risks of pain, sepsis, burns, tetanus and fractures The outfit, in addition to the queer collection of inadequate splints and bandages you refer to, would be in charge of the N C O of a stretcher party who would be responsible to the company officer and/or medical officer

Pain would require morphia in tablet form for oral use and ampoules for injection, if a syringe can be obtained

Sepsis Sulphanilamide in 5 gramme powders in Cellophane packets or 0 5 gramme tablets should be liberally stocked The former for use in wounds, the latter by mouth Indeed sulphanilamide would be a fitting addition to every new first field dressing

Burns —Vaselined gauze sterile in tins, or tannic or acriflavine jelly, can be readily carried in screw top metal jars

Tetanus —In the event of fighting in this country, it is more than probable that the incidence of tetanus will be high Therefore, as immediate evacuation is unlikely, antitetanic serum in ampoules or rubber topped bottles must be available, together with a syringe

Fractures —In every company there are men who have done a first aid course or obtained a certificate from the St John

the usual lesions of skin and mucous membranes are missing Often the break-down of an individual organ—liver, kidneys, heart or brain—is the first symptom of the disease (*b*) Patients carefully treated and probably restored to good health In spite of this their children are of inferior constitution, they may show a poor defence against infections and other harmful environmental influences, hypochromic anæmia, lymphocytosis, monocytosis or abnormalities of the endocrine system

Group 3 does not come within the sphere of premarital and prenatal tests, these patients need the attention of a wise cautious and energetic doctor who will take both a scientific and a social interest in them

Cambridge G **Brock**

IN DEFENCE OF CHLOROFORM

Sir,—Increasingly as time goes on those who write with authority about anæsthetics tend to impose their veto upon the use of chloroform To cite two recent instances Professor Macintosh and Dr Freda Pratt in their textbook issued from the Nuffield Department of Anæsthetics at Oxford devote a bare two pages to chloroform, and that only to banish it, and Dr Langton Hewer, in a broad review of the subject in the *British Journal of Surgery*, states that chloroform is becoming increasingly, and he implies rightly, ousted in favour of "safer" agents Even in Edinburgh, the cradle of chloroformists, the drug is now almost outlawed All this may be merely the swing of the medical pendulum, but I submit that if it is allowed to continue without protest we may find ourselves deprived of one of our most potentially valuable allies, because the oncoming generation of anæsthetists will never learn to use it To encourage these, then, and not with any intention of reviving an old controversy, this plea in defence is entered

For many years in civil life it was my practice, and that, I suspect, of many more others than would be willing to admit it, to use small quantities of chloroform in conjunc- on with nitrous oxide and oxygen in some cases Since orking in the Army I have changed "some" to "all" -that is to say, all cases in which gas and oxygen plus emedication are not enough, and this means practically l soldiers These now number upwards of 500, and n be regarded as a series in that in no case has ether een employed at any stage The surgery done includes l the routine "cold" operations, together with gunshot ounds, accidents and acute abdominal conditions, nd the patients are of a more or less uniform type part from the presence or absence of shock The sults of this procedure, in the opinion of all who come contact with the cases, are unmistakably superior those of the gas-oxygen-ether combination, or of mple open ether I have no statistics to offer, nor do think that in this matter they are of so much value s the evidence of patients and particularly of wardsters, but I am sure that sickness, chest troubles (in far as the anæsthetic used has anything to do with hese), and general postoperative morbidity are reduced a minimum Furthermore, the anæsthetics are more onsistently satisfactory at the time in what may be egarded as a difficult type of patient On the debit ide there has been one case of very mild jaundice lasting few days after a hernia operation—that is all

The contention here put forward is that this is not due ither to luck or to any peculiar skill, but that gas-xygen-chloroform is a safe and a sound anæsthetic, nd one which should not be allowed to fall into disepute The first danger of chloroform—that of sudden ardiac failure during induction—is eliminated because nduction is by gas and oxygen, and the chloroform is nly added slowly later on The second danger—respiratory depression followed by cardiac failure—can rise but in fact does not because the amount of chloroform needed is extremely small and because with practice the early warnings of this condition are easy to detect and to check The third danger, that of damage to the liver and metabolic upset, presumably depends on the concentration and amount of chloroform used, and is a theoretical possibility With the exception of the case of mild jaundice mentioned, and which caused no-one any anxiety, it has never occurred in my experience either in the Army or in civil practice and the risk seems to be at least no greater than that of some of the unfortunate sequelæ of, say, spinal anæsthetics In this connexion it is encouraging to note that M D Nosworthy, speaking of the use of chloroform in patients with prolonged toxæmia, has given the opinion that "if the experimental work were re-done today, taking care to produce smooth anæsthesia with a clear airway and excess oxygen, the toxicity would probably be much less"

Finally, lest I should be accused of luring the young anæsthetist to disaster, I would lay stress on the fact that if the advantages of chloroform are to be enjoyed together with peace of mind, it is essential to learn the technique thoroughly, to practise it carefully, and to work with an adequate apparatus But do not let us drop one of the most valuable members of our team simply because he will get out of hand unless properly managed

TREATMENT OF SUPERFICIAL GRANULATING SURFACES

Sir,—Mr Edmunds in your issue of Aug 2 shows how when a suppurating granulating surface is superficial antiseptic treatment by the Carrel-Dakin method can be accurately applied May I mention another antiseptic method, zinc ionisation which may also be used?

Before beginning treatment microscopic examination is made of smears from various parts of the raw area, especially near the edges (A large number of organisms from one place suggests pocketing under the skin) The area is then measured by tracing its outline on a film of celluloid, placing this on paper ruled in square centimetres and counting the squares covered by the outline Since dosage is important it is necessary to have a certain measure of quantity as a unit For ionisation treatment I chose one milliampere for one minute on a square centimetre and called this a "Leduc" It was found that 40 Leducs sterilised a surface Perhaps less would be sufficient During the last war an attempt was made to abolish suppuration in cases where this was only kept up by an infected discharge It was seldom that the simple condition illustrated by Mr Edmunds presented itself When it did the technique adopted was as follows The skin surrounding the raw area was painted with formalin gelatin as recommended by Sir Almroth Wright in one of his earlier papers Layers of gauze soaked in a sterilised solution of zinc sulphate in gelatin were laid on the raw area to a height of ½ in The gauze slightly overlapped the edge of the skin The positive electrode was kept in contact with the gauze by a bandage At intervals cultures were made from the surface If progress is to be made with this method of treatment it is necessary to determine the average dose which can be relied on to abolish suppuration on an accessible surface This can be done if a sufficient number of cases in which the area can be measured are available In cases where the area cannot be measured—e g, sinuses—the dose can only be estimated The tendency is to give too small a dose

The advantage of zinc ionisation is the speed with which suppuration may disappear Where the area is accessible and the dose is adequate suppuration ceases at once This is due specially to two factors: first, to the fact that zinc albuminate is a bad culture medium for micro-organisms; and secondly, to the absence of irritation of the tissues immediately beneath the actual surface by the treatment

DIAGNOSIS OF CRETINISM

Sir,—Your leading article of Aug. 2 rightly stresses the difficulties that may arise in the diagnosis of cretinism if clinical observation alone is accepted, and the advantage of conducting biological and biochemical tests Some further points may be of interest:—

The precise meaning of the words "cretinism" and "myxœdema" gives rise to some difficulty Presumably a certain clinical state is implied without stating whether the thyroid deficiency is complete or partial Yet if tests are to be interpreted correctly and comparisons made with thyroidectomised animals, such a distinction is important In the absence of suitable methods for detecting circulating thyroid hormone directly, the diagnosis of complete thyroid deficiency in man may only be made with any degree of certainty after elaborate tests during life, combined with post mortem study

tive When it was pointed out that the general public would not be likely to possess copies of these technical publications, the Parliamentary Secretary made the astonishing statement that they could be consulted in local free libraries How many such libraries would stock current editions of either of these expensive works, and would the average purchaser of patent medicines gain any knowledge from consultation of these highly technical treatises ?

Probably one of the greatest abuses in the patent-medicine trade is the licence given to sell well-known drugs under fancy names This abuse was commented on by the Select Committee of 1914, and among others they gave as an example phenolphthalein, which at that date was sold under no less than sixteen fancy names, and the select committee framed the recommendation No 6 “ that fancy names for recognised drugs be subject to regulation ” I sought, in the committee stage, to add a clause carrying out this recommendation It was opposed by two hon members, one of whom very properly disclosed that he had a financial interest in the trade, and the other, a distinguished lawyer, admitted that “ he had been advising some of the trade interests concerned in the arrangements which have resulted in the bill ” Upon the minister declaring that the inclusion of this clause would upset agreements arrived at outside the House, the disturbance of which he strongly deprecated, I withdrew my amendment The minister had declined during the debate to reveal the bodies which it was alleged had come to an agreement in this way, but in a subsequent answer to a question put by me, he gave the list (see *Lancet*, Aug 16, 1941, p 203) For a bill which was to give consideration to the public-health implications of the patent-medicine trade, it is surely remarkable that no opportunity was afforded for the expression of opinion by medical bodies, who are chiefly concerned in the safeguarding of public health

House of Commons E GRAHAM-LITTLE

TREATMENT OF TROOPS AT CIVILIAN V D CLINICS

SIR,—Dr H H White (Aug 16) has called attention to one of the difficulties which often occurs in the treatment of Service V D cases at civilian clinics The lack of cooperation has caused me much concern, the conditions of the last 10 months will, if they continue, result in a considerable proportion of inadequately treated cases I hold a written statement that the civilian clinics will not be held responsible for bad results, but I cannot help feeling that the final situation will be reflected to our disadvantage unless better cooperation can be obtained I have tried to make contact with defaulting cases and have been told that I misunderstood my responsibilities to the Army If a patient fails to attend, I am to infer that he is attending elsewhere for his weekly injection Men attending a week late have told me that they were not allowed off duty on the correct day and cases transferred to me have brought records showing long intervals in their treatment of syphilis I suggest that when a man is transferred to another area, the M O of the civilian clinic which he has been attending and the M O of the clinic in the area to which he is transferred should be *immediately* informed For, in taking on the cases at all, we have a duty to the man quite apart from our “ responsibilities to the Army ”

Often a new case attends with his “ pro forma ” incompletely filled up In any case, every patient calls for individual consideration and the medical officer treating that patient should have a detailed record of previous treatment and of his reaction to that treatment It is absurd to suggest that the civilian clinic is only asked to carry out a prescribed treatment, for the M O of the unit will usually have no special knowledge of V D —in point of fact, I cannot recall a single case referred to me for a prescribed injection I cannot understand why the man should not be given his I 1247 (if desirable, a duplicate I 1247) to be carried to and from the clinic by him on each attendance, this method is effective with civilian cases and it would, if extended to Service cases, overcome most of the difficulties, including that of the man who is returned to his unit long before his records are forwarded from the military hospital The real difficulty is, I think, that the civilian clinics are regarded by the Service authorities as outside their V D schemes but available for intermediate treatment as a conver This inadequate cooperation is apparent in the foll example

A soldier complaining of a discharge from the urethra “ incorrectly ” sent to my clinic by his medical officer found gonococci in the smear, gave sulphathiazole and re the case back to his medical officer The man was, of sent to a military hospital and in due course returned to for surveillance I then found that, in spite of my report, diagnosis “ urethritis ” had been made because were not found at the military hospital after his initial dose Thiazamide

Satisfactory results could be obtained by the utilis of civilian clinics for the routine treatment of cases of venereal disease, but only if Form I 1247 made available and the transfer of cases is no Unless some cooperation is forthcoming medical of of civilian clinics will not be to blame if they tired of trying to maintain some standard of efficien with Service cases

Canterbury DAVID ERSKINE

PREMARITAL AND PRENATAL TESTS

SIR,—I agree with Dr Violet Russell (July 26, p 11 *that there is really no reason why* Wassermann should not form part of the routine examination pregnant women at the antenatal clinics, and it difficult to see why doctors should object to this pro cedure, particularly when the women have no objectio Premarital tests would cause difficulties in many and might have a deterrent effect on the prenatal test I doubt, too, whether a better result would be o if the mother's positive test was discovered marriage It would be interesting to know in Dr Russell's cases how many women per 1000 showed positive result Colonel L W Harrison lately told (*Lancet*, Aug 2, p 136) that in 1939 the number of c of early syphilis dealt with for the first time at civilian centres in England and Wales was 4986, decrease of 45% since 1931, and less than a third of number in 1920 He also showed that there was decline in the role of syphilis in killing infants, th death-rate from this cause had fallen from 2 03 per 10 in 1917 to 0 2 in 1939 My own experience at infant-welfare centres during 28 years bears out Col Harrison's observations I saw remarkably few which showed clinical signs of congenital syphilis Ca of marasmus with snuffles and sore buttocks, which I taught to regard as syphilitic in my student days, referred to hospital for Wassermann tests, but in not single case was the result positive Doctors at welfare centres could give us some valuable figures this important point

Kensington RONALD CARTER

SIR,—Your leading article of July 12 raises an portant question You quote opponents of s interference as casting doubts on the hundred-per-c reliability of any particular test or combination of There is no hundred-per-cent reliability either biology or in sociology—trade, commerce e politics and so on As regards the liberty of the s and professional secrecy, we do not need legal pulsion, a sixpenny book adequately composed and common sense of the British people should be e The main difficulty originates from the nature of disease, which covers the whole gamut of warfare fr the deadly surprise raid to the trench-warfare of s biosis We distinguish by examination —

(1) Patients with clinical symptoms and serological evid

(2) Patients without clinical symptoms but with logical evidence These include patients treated factorily and patients infected in a peculiar way—e g women who conceive a syphilitic child from a syph husband, or the children born of a syphilitic *mother* are not contaminated by the direct implantation of specific germ but by absorption of an antigen anti mixture, thus the reaction is less powerful and the sy matology wholly altered

(3) Patients with neither clinical symptoms nor sero evidence (*a*) Patients with latent disease who are because they often do not know they are ill and inf and their victims do not know they are infected M the virulence of the infectious factor is diminished, and

the usual lesions of skin and mucous membranes are missing Often the break-down of an individual organ—liver, kidneys, heart or brain—is the first symptom of the disease (*b*) Patients carefully treated and probably restored to good health In spite of this their children are of inferior constitution, they may show a poor defence against infections and other harmful environmental influences, hypochromic anæmia, lymphocytosis, monocytosis or abnormalities of the endocrine system

Group 3 does not come within the sphere of premarital and prenatal tests, these patients need the attention of a wise cautious and energetic doctor who will take both a scientific and a social interest in them

TREATMENT OF SUPERFICIAL GRANULATING SURFACES

Sir —Mr Edmunds in your issue of Aug 2 shows how when a suppurating granulating surface is superficial antiseptic treatment by the Carrel-Dakin method can be accurately applied May I mention another antiseptic method zinc ionisation which may also be used ?

Before beginning treatment microscopic examination is made of smears from various parts of the raw area, especially near the edges (A large number of organisms from one place suggests pocketing under the skin) The area is then measured by tracing its outline on a film of celluloid, placing this on paper ruled in square centimetres and counting the squares covered by the outline Since dosage is important it is necessary to have a certain measure of quantity as a unit For ionisation treatment I chose one milliampere for one minute on a square centimetre and called this a "Leduc" It was found that 40 Leducs sterilised a surface Perhaps less would be sufficient During the last war an attempt was made to abolish suppuration in cases where this was only kept up by an infected discharge It was seldom that the simple condition illustrated by Mr Edmunds presented itself When it did the technique adopted was as follows The skin surrounding the raw area was painted with formalin gelatin as recommended by Sir Almroth Wright in one of his earlier papers Layers of gauze soaked in a sterilised solution of zinc sulphate in gelatin were laid on the raw area to a height of ½ in. The gauze slightly overlapped the edge of the skin The positive electrode was kept in contact with the gauze by a bandage. At intervals cultures were made from the surface If progress is to be made with this method of treatment it is necessary to determine the average dose which can be relied on to abolish suppuration on an accessible surface This can be done if a sufficient number of cases in which the area can be measured are available In cases where the area cannot be measured—e g , sinuses—the dose can only be estimated The tendency is to give too small a dose

The advantage of zinc ionisation is the speed with which suppuration may disappear Where the area is accessible and the dose is adequate suppuration ceases at once. This is due specially to two factors: first, to the fact that zinc albuminate is a bad culture medium for micro-organisms; and secondly, to the absence of irritation of the tissues immediately beneath the actual surface by the treatment

TREATMENT OF SUPERFICIAL GRANULATING SURFACES

SIR —Mr Edmunds in your issue of Aug 2 shows how when a suppurating granulating surface is superficial antiseptic treatment by the Carrel-Dakin method can be accurately applied May I mention another antiseptic method zinc ionisation which may also be used ?

Before beginning treatment microscopic examination is made of smears from various parts of the raw area. especially near the edges (A large number of organisms from one place suggests pocketing under the skin) The area is then measured by tracing its outline on a film of celluloid placing this on paper ruled in square centimetres and counting the squares covered by the outline Since dosage is important it is necessary to have a certain measure of quantity as a unit. For ionisation treatment I chose one milliampere for one minute on a square centimetre and called this a "Leduc" It was found that 40 Leducs sterilised a surface Perhaps less would be sufficient During the last war an attempt was made to abolish suppuration in cases where this was only kept up by an infected discharge It was seldom that the simple condition illustrated by Mr. Edmunds presented itself When it did the technique adopted was as follows The skin surrounding the raw area was painted with formalin gelatin as recommended by Sir Almroth Wright in one of his earlier papers Layers of gauze soaked in a sterilised solution of zinc sulphate in gelatin were laid on the raw area to a height of $\frac{1}{2}$ in. The gauze slightly overlapped the edge of the skin The positive electrode was kept in contact with the gauze by a bandage. At intervals cultures were made from the surface If progress is to be made with this method of treatment it is necessary to determine the average dose which can be relied on to abolish suppuration on an accessible surface This can be done if a sufficient number of cases in which the area can be measured are available. In cases where the area cannot be measured—e.g , sinuses—the dose can only be estimated The tendency is to give too small a dose

The advantage of zinc ionisation is the speed with which suppuration may disappear Where the area is accessible and the dose is adequate suppuration ceases at once. This is due specially to two factors : first, to the fact that zinc albuminate is a bad culture medium for micro-organisms ; and secondly, to the absence of irritation of the tissues immediately beneath the actual surface by the treatment.

Sidmouth.   A. R FRIEL

DIAGNOSIS OF CRETINISM

SIR.—Your leading article of Aug. 2 rightly stresses the difficulties that may arise in the diagnosis of cretinism if clinical observation alone is accepted, and the advantage of conducting biological and biochemical tests Some further points may be of interest :—

The precise meaning of the words "cretinism" and "myxœdema" gives rise to some difficulty Presumably a certain clinical state is implied without stating whether the thyroid deficiency is complete or partial Yet if tests are to be interpreted correctly and comparisons made with thyroidectomised animals, such a distinction is important In the absence of suitable methods for detecting circulating thyroid hormone directly, the diagnosis of complete thyroid deficiency in man may only be made with any degree of certainty after elaborate tests during life, combined with post mortem study

tive When it was pointed out that the general public would not be likely to possess copies of these technical publications, the Parliamentary Secretary made the astonishing statement that they could be consulted in local free libraries How many such libraries would stock current editions of either of these expensive works, and would the average purchaser of patent medicines gain any knowledge from consultation of these highly technical treatises ?

Probably one of the greatest abuses in the patent-medicine trade is the licence given to sell well-known drugs under fancy names This abuse was commented on by the Select Committee of 1914, and among others they gave as an example phenolphthalein which at that date was sold under no less than sixteen fancy names, and the select committee framed the recommendation No 6 " that fancy names for recognised drugs be subject to regulation " I sought, in the committee stage, to add a clause carrying out this recommendation It was opposed by two hon members, one of whom very properly disclosed that he had a financial interest in the trade, and the other, a distinguished lawyer, admitted that " he had been advising some of the trade interests concerned in the arrangements which have resulted in the bill " Upon the minister declaring that the inclusion of this clause would upset agreements arrived at outside the House, the disturbance of which he strongly deprecated, I withdrew my amendment The minister had declined during the debate to reveal the bodies which it was alleged had come to an agreement in this way, but in a subsequent answer to a question put by me, he gave the list (see *Lancet*, Aug 16, 1941, p 203) For a bill which was to give consideration to the public-health implications of the patent-medicine trade, it is surely remarkable that no opportunity was afforded for the expression of opinion by medical bodies, who are chiefly concerned in the safeguarding of public health

House of Commons E GRAHAM-LITTLE

TREATMENT OF TROOPS AT CIVILIAN V D CLINICS

SIR,—Dr H H White (Aug 16) has called attention to one of the difficulties which often occurs in the treatment of Service V D cases at civilian clinics The lack of cooperation has caused me much concern, the conditions of the last 10 months will, if they continue, result in a considerable proportion of inadequately treated cases I hold a written statement that the civilian clinics will not be held responsible for bad results, but I cannot help feeling that the final situation will be reflected to our disadvantage unless better cooperation can be obtained I have tried to make contact with defaulting cases and have been told that I misunderstood my responsibilities to the Army If a patient fails to attend, I am to infer that he is attending elsewhere for his weekly injection Men attending a week late have told me that they were not allowed off duty on the correct day and cases transferred to me have brought records showing long intervals in their treatment of syphilis I suggest that when a man is transferred to another area, the M O of the civilian clinic which he has been attending and the M O of the clinic in the area to which he is transferred should be *immediately* informed For, in taking on the cases at all, we have a duty to the man quite apart from our " responsibilities to the Army "

Often a new case attends with his " pro forma " incompletely filled up In any case, every patient calls for individual consideration and the medical officer treating that patient should have a detailed record of previous treatment and of his reaction to that treatment It is absurd to suggest that the civilian clinic is only asked to carry out a prescribed treatment, for the M O of the unit will usually have no special knowledge of V D —in point of fact, I cannot recall a single case referred to me for a prescribed injection I cannot understand why the man should not be given his I 1247 (if desirable, a duplicate I 1247) to be carried to and from the clinic by him on each attendance , this method is effective with civilian cases and it would, if extended to Service cases, overcome most of the difficulties, including that of the man who is returned to his unit long before his records are forwarded from the military hospital The real difficulty is, I think, that the civilian clinics are regarded by the Service authorities as outside their V D schemes but available for intermediate treatment as a convenie This inadequate cooperation is apparent in the follo example

A soldier complaining of a discharge from the urethra " incorrectly " sent to my clinic by his medical officer found gonococci in the smear, gave sulphathiazole and refe the case back to his medical officer The man was, of cou sent to a military hospital and in due course returned to for surveillance I then found that, in spite of my report, diagnosis " urethritis " had been made because gonoco were not found at the military hospital after his initial dose Thiazamide

Satisfactory results could be obtained by the utilisati of civilian clinics for the routine treatment of Se cases of venereal disease, but only if Form I 1247 made available and the transfer of cases is notifi Unless some cooperation is forthcoming medical office of civilian clinics will not be to blame if they beco tired of trying to maintain some standard of efficien with Service cases

Canterbury DAVID ERSKINE

PREMARITAL AND PRENATAL TESTS

SIR —I agree with Dr Violet Russell (July 26, p 1 that there is really no reason why Wassermann tes should not form part of the routine examination pregnant women at the antenatal clinics, and it difficult to see why doctors should object to this pr cedure, particularly when the women have no objectio Premarital tests would cause difficulties in many case and might have a deterrent effect on the prenatal test I doubt, too, whether a better result would be obtaine if the mother's positive test was discovered befor marriage It would be interesting to know in Dr Russell's cases how many women per 1000 showed positive result Colonel L W Harrison lately told (*Lancet*, Aug 2, p 136) that in 1939 the number of cas of early syphilis dealt with for the first time at t civilian centres in England and Wales was 4986, decrease of 45% since 1931 and less than a third of t number in 1920 He also showed that there was decline in the role of syphilis in killing infants, th death-rate from this cause had fallen from 2 03 per 10 in 1917 to 0 2 in 1939 My own experience at t infant-welfare centres during 28 years bears out Colo Harrison's observations I saw remarkably few ca which showed clinical signs of congenital syphilis Ca of marasmus with snuffles and sore buttocks, which I w taught to regard as syphilitic in my student days referred to hospital for Wassermann tests, but in no single case was the result positive Doctors at infa welfare centres could give us some valuable figures this important point

Kensington RONALD CARTER

SIR,—Your leading article of July 12 raises an portant question You quote opponents of st interference as casting doubts on the hundred per c reliability of any particular test or combination of te There is no hundred-per-cent reliability either biology or in sociology—trade commerce, econo politics and so on As regards the liberty of the sub and professional secrecy, we do not need legal c pulsion , a sixpenny book adequately composed and common sense of the British people should be eno The main difficulty originates from the nature of disease, which covers the whole gamut of warfare f the deadly surprise raid to the trench-warfare of s biosis We distinguish by examination :—

(1) Patients with clinical symptoms and serological evide

(2) Patients without clinical symptoms but with logical evidence These include patients treated uns factorily and patients infected in a peculiar way—e g women who conceive a syphilitic child from a syph husband, or the children born of a syphilitic mother are not contaminated by the direct implantation of specific germ but by absorption of an antigen anti mixture , thus the reaction is less powerful and the sym matology wholly altered

(3) Patients with neither clinical symptoms nor serolo evidence (*a*) Patients with latent disease who are dange because they often do not know they are ill and infecti and their victims do not know they are infected Moreo the virulence of the infectious factor is diminished, and t

the usual lesions of skin and mucous membranes are missing Often the break-down of an individual organ—liver, kidneys, heart or brain—is the first symptom of the disease (*b*) Patients carefully treated and probably restored to good health In spite of this their children are of inferior constitution, they may show a poor defence against infections and other harmful environmental influences, hypochromic anæmia, lymphocytosis, monocytosis or abnormalities of the endocrine system

Group 3 does not come within the sphere of premarital and prenatal tests; these patients need the attention of a wise cautious and energetic doctor who will take both a scientific and a social interest in them

Cambridge G Brock.

IN DEFENCE OF CHLOROFORM

Sir,—Increasingly as time goes on those who write with authority about anæsthetics tend to impose their veto upon the use of chloroform To cite two recent instances Professor Macintosh and Dr Freda Pratt in their textbook issued from the Nuffield Department of Anæsthetics at Oxford devote a bare two pages to chloroform, and that only to banish it; and Dr Langton Hewer, in a broad review of the subject in the *British Journal of Surgery* states that chloroform is becoming increasingly, and he implies rightly, ousted in favour of "safer" agents Even in Edinburgh, the cradle of chloroformists the drug is now almost outlawed All this may be merely the swing of the medical pendulum, but I submit that if it is allowed to continue without protest we may find ourselves deprived of one of our most potentially valuable allies, because the oncoming generation of anæsthetists will never learn to use it To encourage these, then and not with any intention of reviving an old controversy, this plea in defence is entered

For many years in civil life it was my practice, and that, I suspect, of many more others than would be willing to admit it, to use small quantities of chloroform in conjunction with nitrous oxide and oxygen in some cases Since working in the Army I have changed "some" to "all" —that is to say, all cases in which gas and oxygen plus premedication are not enough, and this means practically all soldiers These now number upwards of 500, and can be regarded as a series in that in no case has ether been employed at any stage The surgery done includes l the routine "cold" operations, together with gunshot ounds, accidents and acute abdominal conditions, nd the patients are of a more or less uniform type part from the presence or absence of shock. The esults of this procedure, in the opinion of all who come n contact with the cases, are unmistakably superior o those of the gas-oxygen-ether combination, or of mple open ether I have no statistics to offer, nor do think that in this matter they are of so much value s the evidence of patients and particularly of ward-sters, but I am sure that sickness, chest troubles (in o far as the anæsthetic used has anything to do with hese), and general postoperative morbidity are reduced o a minimum Furthermore the anæsthetics are more onsistently satisfactory at the time in what may be egarded as a difficult type of patient On the debit ide there has been one case of very mild jaundice lasting few days after a hernia operation—that is all

The contention here put forward is that this is not due ither to luck or to any peculiar skill, but that gas-oxygen-chloroform is a safe and a sound anæsthetic nd one which should not be allowed to fall into disepute The first danger of chloroform—that of sudden cardiac failure during induction—is eliminated because nduction is by gas and oxygen and the chloroform is only added slowly later on The second danger—respiratory depression followed by cardiac failure—can arise but in fact does not because the amount of chloroform needed is extremely small and because with practice the early warnings of this condition are easy to detect and to check The third danger that of damage to the liver and metabolic upset, presumably depends on the concentration and amount of chloroform used, and is a theoretical possibility With the exception of the case of mild jaundice mentioned and which caused no-one any anxiety it has never occurred in my experience either in the Army or in civil practice and the risk seems to be at least no greater than that of some of the unfortunate sequelæ of, say, spinal anæsthetics In this connexion it is encouraging to note that M D Nosworthy speaking of the use of chloroform in patients with prolonged toxæmia, has given the opinion that "if the experimental work were re-done today, taking care to produce smooth anæsthesia with a clear airway and excess oxygen, the toxicity would probably be much less

Finally lest I should be accused of luring the young anæsthetist to disaster, I would lay stress on the fact that if the advantages of chloroform are to be enjoyed together with peace of mind, it is essential to learn the technique thoroughly, to practise it carefully, and to work with an adequate apparatus But do not let us drop one of the most valuable members of our team simply because he will get out of hand unless properly managed

D H Belfrage

TREATMENT OF SUPERFICIAL GRANULATING SURFACES

Sir,—Mr Edmunds in your issue of Aug 2 shows how when a suppurating granulating surface is superficial antiseptic treatment by the Carrel-Dakin method can be accurately applied May I mention another antiseptic method zinc ionisation which may also be used?

Before beginning treatment microscopic examination is made of smears from various parts of the raw area, especially near the edges (A large number of organisms from one place suggests pocketing under the skin) The area is then measured by tracing its outline on a film of celluloid, placing this on paper ruled in square centimetres and counting the squares covered by the outline Since dosage is important it is necessary to have a certain measure of quantity as a unit For ionisation treatment I chose one milliampere for one minute on a square centimetre and called this a "Leduc" It was found that 40 Leducs sterilised a surface Perhaps less would be sufficient During the last war an attempt was made to abolish suppuration in cases where this was only kept up by an infected discharge It was seldom that the simple condition illustrated by Mr Edmunds presented itself When it did the technique adopted was as follows The skin surrounding the raw area was painted with formalin gelatin as recommended by Sir Almroth Wright in one of his earlier papers Layers of gauze soaked in a sterilised solution of zinc sulphate in gelatin were laid on the raw area to a height of $\frac{1}{2}$ in. The gauze slightly overlapped the edge of the skin The positive electrode was kept in contact with the gauze by a bandage. At intervals cultures were made from the surface If progress is to be made with this method of treatment it is necessary to determine the average dose which can be relied on to abolish suppuration on an accessible surface This can be done if a sufficient number of cases in which the area can be measured are available In cases where the area cannot be measured—e g, sinuses—the dose can only be estimated The tendency is to give too small a dose

The advantage of zinc ionisation is the speed with which suppuration may disappear Where the area is accessible and the dose is adequate suppuration ceases at once. This is due specially to two factors: first, to the fact that zinc albuminate is a bad culture medium for micro-organisms; and secondly, to the absence of irritation of the tissues immediately beneath the actual surface by the treatment

(2) Patients without clinical symptoms but with logical evidence These include patients treated factorily and patients infected in a peculiar way—e g women who conceive a syphilitic child from a husband, or the children born of a syphilitic mother are not contaminated by the direct implantation of specific germ but by absorption of an antigen antib mixture, thus the reaction is less powerful and the sym matology wholly altered

(3) Patients with neither clinical symptoms nor evidence (*a*) Patients with latent disease who are because they often do not know they are ill and infecti and their victims do not know they are infected Moreo the virulence of the infectious factor is diminished, and

1939 He also held the appointments of radiologist to the Hospital for Sick Children, Great Ormond Street, and consulting radiologist to the Infants Hospital, Vincent Square Dr Shires leaves a widow and three children

A colleague writes Those who worked with Bertram Shires knew that they could obtain from him shrewd clinical judgment apart from his expert radiological opinion At St Thomas's we mourn a loyal friend and a colleague on whose level-headed advice we could always count Always an indefatigable worker, during the war Shires had undertaken responsibilities which probably helped to bring about his untimely end

Public Health

Poliomyelitis in Slough

SINCE July 15 there have been 33 cases of poliomyelitis in the Slough district, 17 being in the borough itself and the remainder in Stoke Poges and Wexham, with 1 in Datchett and 1 in Taplow Most of the cases have been in children, the youngest being aged 3 years, but there was one patient aged 16, one 18 and one 30 There have been two deaths, both in children The first died 4 days after the onset, the second developed sudden respiratory paralysis on the morning of the fourth day and in spite of treatment in a Both respirator died with cardiac failure early next morning There have been three households with two proved cases each One of the children who died developed the disease on Aug 11 and his elder brother developed it on Aug 19 The cerebrospinal fluid has shown an increase in cells in all cases ranging from 23 to 700 per c mm , mostly lymphocytes The cell-count has borne no apparent relation to the severity , some cases with high counts have aborted and some of the worst have shown only a few cells The earlier cases had an unusually long meningeal stage All the patients have been treated with M & B 693, and it is hoped to use convalescent serum in addition when supplies come through from Harrogate

Infectious Disease in England and Wales

WEEK ENDED AUGUST 9

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 804 , whooping-cough, 3138 , diphtheria, 677 , paratyphoid 150 , typhoid, 38 , measles (excluding rubella), 2276 , pneumonia (primary or influenzal), 408 , puerperal pyrexia, 127 , cerebrospinal fever, 121 , poliomyelitis, 30 polio-encephalitis, 2 , encephalitis lethargica, 3 , dysentery, 40 , ophthalmia neonatorum, 72 No case of cholera, plague or typhus fever was notified during the week

Deaths —In 126 great towns there were 3 (2) deaths from enteric fever, 2 (0) from scarlet fever 19 (3) from whooping-cough, 2 (0) from measles, 18 (1) from diphtheria, 51 (3) from diarrhœa and enteritis under 2 years, and 2 (0) from influenza The figures in parentheses are those for London itself

Leicester reported 1 fatal case of enteric fever There were 4 deaths from diphtheria at Liverpool Birmingham and Nottingham each reported 5 deaths from diarrhœa and enteritis under 2 years

The number of stillbirths notified during the week was 192 (corresponding to a rate of 42 per thousand total births), including 14 in London

---

GERMAN BIRTHS, MARRIAGES AND DEATHS —The *Deutsche Medizinische Wochenschrift* for July 4 (p 742) gives a brief survey of German vital statistics for the first quarter of 1941 In the great towns of Germany in this period there were 10 2 marriages per 1000 of the population This was 0 1 more than in the same period of 1939 There were 15 3 births per 1000 of the population, an increase of 4 1 on the same period for 1933 but a fall of 4 from the first quarter of 1940 and of 1 9 from the first quarter of 1939 The death rate was 14 5 per 1000, which was 2 less than for the same quarter in 1940 and 0 8 less than for the same quarter of 1939 This decrease is attributed to a fall in the deaths from pulmonary infections, heart diseases, apoplexy and old age

Notes, Comments and Abstracts

APPARATUS FOR SUCTION DRAINAGE

ARTHUR EDMUNDS,* C B , M S LOND , F R C S

THE apparatus here described was designed for the treatment of empyema by suction drainage It embodies no new principles but it has the great advantage that the materials for its construction are easily obtainable and their cost is negligible Its manufacture presents no difficulty to anyone who can use a soldering iron

Two large tins (A and B in fig 1) are required—five-gallon Dettol tins answer the purpose admirably These tins have a filling inlet E and a tap for withdrawing the fluid This outlet tap is not used for the present purpose Into each tin two short lengths of brass tube are soldered, one at the top and one at the bottom (*a a′*, *b b′*) Dettol tins are not quite thick enough to support the brass tubes, and the junction should be reinforced by a copper plate about as big as a penny, the whole being "sweated" together The two lower tubes are connected by a rubber tube C, controlled by a screw tap D Over each filling inlet E a piece of thin sheet rubber is fastened—the wrist part of an ordinary operating glove does quite well and it can be fastened in position by the thickened edge of the glove or a rubber band

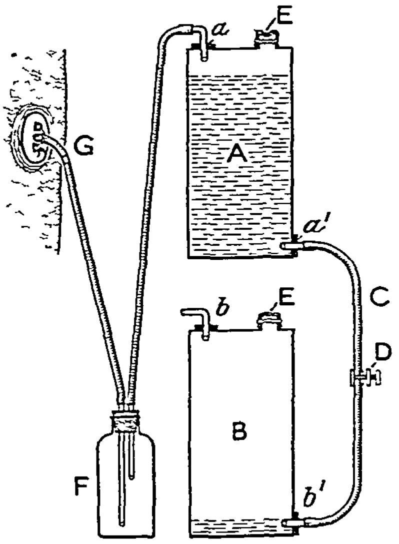

FIG 1

If tin A is filled with water and put on a stand a short distance above B, on opening the screw tap D water flows from A to B, and air is aspirated through *a* If both upper tubes are freely open the rubber diaphragms over the inlet openings are flat, but if there is any resistance to the ingress of air through the upper tube (*a*) the diaphragm on tin A will become concave

The suction apparatus thus arranged is connected to the drainage tube G which goes into the pleural cavity, a bottle F with two tubes through the stopper, or a Woulfe's bottle, being interposed to catch the discharge If the negative pressure in the pleural cavity is to be maintained, the junction between the drainage tube and the chest wall must be as airtight as possible A good junction can be made as follows

Cut some pieces of lint into discs about 4 in in diameter, with a hole in the centre of such a size that the drainage tube fits reasonably tightly These pieces of lint are soaked in melted Vaseline, which is allowed to cool on them so that they are heavily charged with it A piece of sheet tin is also wanted with a hole in the centre through which the drainage tube can pass A small wire ring is soldered on each side of this hole The method of assembling these parts is shown in fig 2, which represents them in diagrammatic section The tube L coming through the chest wall H passes through the lint J and then through the tin plate K A silkworm gut suture is tied to the loops on this plate (*k k′*) and then tied firmly round the drainage tube The whole is then strapped to the chest wall with elastic strapping Gauze, wool and a manytail bandage are applied around the whole of this to absorb any leaking fluid and to keep the vaseline from soiling sheets The whole will need changing every three or four days

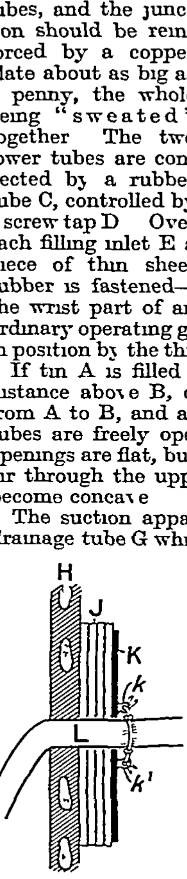

FIG 2

The degree of negative pressure can be regulated by the difference of level between the two tins When the upper tin is empty all that is necessary is to reverse the in the untreated state There seems little doubt, however, that in some cases thyroid deficiency is not complete, thus a "cretin" aged 9 at present under observation shows B M R — 38%, serum cholesterol 450 mg per 100 c cm, and no response to injected thyrotrophic hormone, yet the electrocardiogram shows no changes after 10 months without thyroid

Although the urinary creatine is a valuable index of the response of the thyroid, considerable experience of the use of thyrotrophic hormone over the last 4 years has suggested to us that clinical observation of the pulse rate, temperature, *size of thyroid gland &c is sufficient if a potent preparation is used in adequate quantities* (*Quart J Med*, 1939, 8, 195), and there seems no reason why this valuable test should not be applied in the outpatient department or in practice It should be remembered, however, that there are cases with low basal metabolic rates and structurally normal thyroid glands who are resistant to the stimulation of thyrotrophic extracts

No mention is made in your article of the electrocardiographic changes in cretinism Although the evidence is not yet complete, it seems likely that in man and the rabbit total absence of the thyroid is always associated with characteristic changes, though the converse is not necessarily true—i e, that the presence of the typical electrocardiogram means total absence of thyroid secretion During the first year of life, the simplest confirmatory tests of thyroid deficiency appear to be a study of the development of the centres of ossification and the electrocardiogram, the characteristic low-voltage graph is not likely to be due to other causes at this age Cases of dwarfism and mental retardation diagnosed as cretins on clinical grounds and treated with thyroid for years are often seen, and present a difficult problem In the treated state, of course, all tests will be negative except an absence of response to injected thyrotrophic extract if no thyroid gland is present To establish the diagnosis, thyroid extract may have to be withheld and serial electrocardiographic, biochemical and metabolic studies made In man and the rabbit it may take 80 days or longer for typical electrocardiographic changes to appear after withdrawing all thyroid

Finally, more sensitive methods of assay have demonstrated the presence of circulating thyrotrophic substances in some subjects with thyroid deficiency (Collard, H B et al *Clin Sci* 1940, 4, 323), and if the thyroid behaves in a similar manner to the gonadal system in suppressing pituitary activity in regard to its own stimulating substance, then a further test may be evolved to help in distinguishing between cases of complete and partial thyroid deficiency

TRAINING AND EMPLOYMENT FOR THE DISABLED

IN a circular (N 2449) issued on Aug 14 the Ministry of Health explain the arrangements they have made with the Ministry of Labour for the resettlement and vocational training of the disabled

The Ministry of Labour already administer a scheme of vocational training in occupations connected with munitions, and this is available for disabled people who are capable of taking the courses In addition, the ministry proposes to set up special training courses covering a wider range of occupations for disabled people only The scheme will be open to men and women over 16 who are unable because of disablement to resume their former occupations Training will be given at the ministry's own centres, at institutions specialising in the training of cripples, at technical colleges administered by local education authorities, and by arrangements made with individual employers The scheme will not be limited to members of the Forces and civil defence services, or civilians disabled by enemy action, but will include people disabled in industry or through other causes Training will be limited at present to those who appear likely, when trained, to obtain employment under ordinary industrial conditions Arrangements for training will be made by employment exchanges, who will send a representative to interview a patient on being notified by his hospital The exchanges will also advise patients who do not need special training but require information about returning to their previous employment or taking up some other

Obituary

CHARLES ARCHIBALD SCOTT RIDOUT

M S LOND, F R C S

Mr C A Scott Ridout of Southsea, who died on Aug 9 after a trying illness of some three months, was the son of the late Staff Surgeon Charles Lyon Ridout, R N He was born in Devon in 1875 and educated at Sherborne, where he played for the cricket XI and the rugby XV He qualified M R C S from Bart's in 1899, and took his London degree two years later While holding house-appointments in the throat department at Bart's and at the North Staffordshire Infirmary and Eye Hospital he continued to equip himself for his specialty, obtaining his M S in 1903 and in 1904 the F R C S and a Jeaffreson exhibition In this same year he also began his long association with the Royal Portsmouth Hospital Two years later he was appointed honorary pathologist and soon he was elected to the surgical staff He also became surgeon to the Portsmouth and Southern Counties Eye and Ear Hospital, where he was later in charge of the aural and throat department During the last war he served, with the rank of major, as a surgeon specialist at the 5th Southern General Hospital at Portsmouth, and later with the 29th Stationary Hospital in Salonika and Italy, finally returning to Portsmouth as divisional surgical officer for ear, nose and throat cases

A G O writes As Scott Ridout's junior it was my privilege to watch his methods and admire his keenness and energy He was anxious to encourage and help his juniors in every way, and later on, when our paths in surgery diverged, it was always a pleasure when he dropped in of an evening to discourse on some particular case and discuss its bearing in other fields of surgery The time came when as a patient I saw how his amazing energy seemed to be entirely directed to each individual patient and how despite his busy life he found time to cheer and encourage one's relatives and help to relieve their anxiety

FRANK HAYDON

L R C P

Dr Haydon, who died at Bideford on Aug 1 in his eightieth year, was for over 35 years secretary to the court of examiners of the Society of Apothecaries During his period of office from 1895 to 1930 the smooth working of the examinations was largely due to his careful organisation' Many candidates will remember him for his courtesy, and he was always sympathetic to those who were referred Soon after he qualified from the Westminster Hospital in 1891 Dr Haydon became interested in ophthalmology, and after holding a clinical assistantship at Moorfields he was for five years assistant surgeon to the Western Ophthalmic Hospital For many years he was also examiner of eyesight to the London and South Western Railway (later the Southern Railway) and his statistical eyesight tables and Railway Test Type Case were based on this experience He also compiled an ophthalmic atlas for recording pathological conditions of the fundus by means of superimposed layers of colour

BERTRAM SHIRES

M B EDIN, D M R E

Dr Shires, who died at his house in Wimpole Street on Aug 8, was one of the band of consultants who continued to live in London in spite of the war His work at St Thomas's Hospital in London and Godalming, and at Great Ormond Street took up almost the whole of his time, and entailed much exhausting travelling, while at the end of a tiring day he would take his turn at fire-watching On the day of his death, after a night of pain, he drove himself to Godalming and put in an afternoon's work there He died in his sleep the same night

Bertram Shires had qualified in medicine at Edinburgh just before the last war, and he joined the R A M C to serve as a major When he returned to civil life he took up radiology and obtained the Cambridge D M R E in 1921 He joined the X-ray department at St Thomas's in 1924 as chief assistant, becoming assistant radiologist in 1927, and director of the department in

1939 He also held the appointments of radiologist to the Hospital for Sick Children, Great Ormond Street, and consulting radiologist to the Infants Hospital, Vincent Square Dr Shires leaves a widow and three children

A colleague writes Those who worked with Bertram Shires knew that they could obtain from him shrewd clinical judgment apart from his expert radiological opinion At St Thomas's we mourn a loyal friend and a colleague on whose level-headed advice we could always count Always an indefatigable worker, during the war Shires had undertaken responsibilities which probably helped to bring about his untimely end

Public Health

Poliomyelitis in Slough

SINCE July 15 there have been 33 cases of poliomyelitis in the Slough district, 17 being in the borough itself and the remainder in Stoke Poges and Wexham, with 1 in Datchett and 1 in Taplow Most of the cases have been in children, the youngest being aged 3 years, but there was one patient aged 16, one 18 and one 30 There have been two deaths, both in children The first died 4 days after the onset, the second developed sudden respiratory paralysis on the morning of the fourth day and in spite of treatment in a Both respirator died with cardiac failure early next morning There have been three households with two proved cases each One of the children who died developed the disease on Aug 11 and his elder brother developed it on Aug 19 The cerebrospinal fluid has shown an increase in cells in all cases ranging from 23 to 700 per c mm , mostly lymphocytes The cell-count has borne no apparent relation to the severity , some cases with high counts have aborted and some of the worst have shown only a few cells The earlier cases had an unusually long meningeal stage All the patients have been treated with M & B 693, and it is hoped to use convalescent serum in addition when supplies come through from Harrogate

Infectious Disease in England and Wales

WEEK ENDED AUGUST 9

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 804 , whooping-cough, 3138 , diphtheria, 677 , paratyphoid 150 , typhoid, 38 , measles (excluding rubella), 2276 , pneumonia (primary or influenzal), 408 , puerperal pyrexia, 127 , cerebrospinal fever, 121 , poliomyelitis, 30 , polio-encephalitis, 2 , encephalitis lethargica, 3 , dysentery, 40 , ophthalmia neonatorum 72 No case of cholera, plague or typhus fever was notified during the week

Deaths —In 126 great towns there were 3 (2) deaths from enteric fever, 2 (0) from scarlet fever 19 (3) from whooping-cough, 2 (0) from measles, 18 (1) from diphtheria, 51 (3) from diarrhœa and enteritis under 2 years, and 2 (0) from influenza The figures in parentheses are those for London itself

Leicester reported 1 fatal case of enteric fever There were 4 deaths from diphtheria at Liverpool Birmingham and Nottingham each reported 5 deaths from diarrhœa and enteritis under 2 years

The number of stillbirths notified during the week was 192 (corresponding to a rate of 42 per thousand total births), including 14 in London

---

GERMAN BIRTHS, MARRIAGES AND DEATHS —The *Deutsche Medizinische Wochenschrift* for July 4 (p 742) gives a brief survey of German vital statistics for the first quarter of 1941 In the great towns of Germany in this period there were 10 2 marriages per 1000 of the population This was 0 1 more than in the same period of 1939 There were 15 3 births per 1000 of the population, an increase of 4 1 on the same period for 1933 but a fall of 4 from the first quarter of 1940 and of 1 9 from the first quarter of 1939 The death rate was 14 5 per 1000, which was 2 less than for the same quarter in 1940 and 0 8 less than for the same quarter of 1939 This decrease is attributed to a fall in the deaths from pulmonary infections, heart diseases, apoplexy and old age

Notes, Comments and Abstracts

APPARATUS FOR SUCTION DRAINAGE

ARTHUR EDMUNDS, C B , M S LOND , F R C S

THE apparatus here described was designed for the treatment of empyema by suction drainage It embodies no new principles but it has the great advantage that the materials for its construction are easily obtainable and their cost is negligible Its manufacture presents no difficulty to anyone who can use a soldering iron

Two large tins (A and B in fig 1) are required—five gallon Dettol tins answer the purpose admirably These tins have a filling inlet E and a tap for withdrawing the fluid This outlet tap is not used for the present purpose Into each tin two short lengths of brass tube are soldered, one at the top and one at the bottom (*a a′*, *b b′*) Dettol tins are not quite thick enough to support the brass tubes, and the junction should be reinforced by a copper plate about as big as a penny, the whole being "sweated" together The two lower tubes are connected by a rubber tube C, controlled by a screw tap D Over each filling inlet E a piece of thin sheet rubber is fastened—the wrist part of an ordinary operating glove does quite well and it can be fastened in position by the thickened edge of the glove or a rubber band

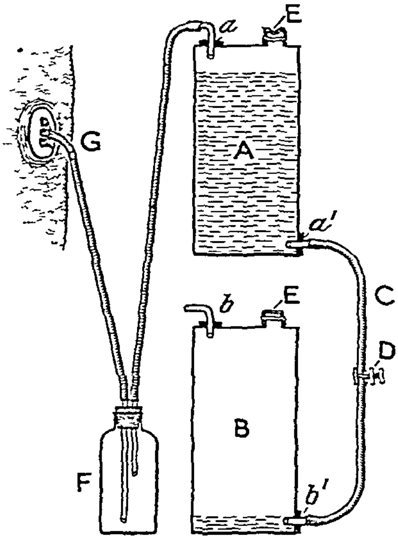

FIG 1

If tin A is filled with water and put on a stand a short distance above B, on opening the screw tap D water flows from A to B, and air is aspirated through *a* If both upper tubes are freely open the rubber diaphragms over the inlet openings are flat, but if there is any resistance to the ingress of air through the upper tube (*a*) the diaphragm on tin A will become concave

The suction apparatus thus arranged is connected to the drainage tube G which goes into the pleural cavity, a bottle F with two tubes through the stopper, or a Woulfe's bottle, being interposed to catch the discharge If the negative pressure in the pleural cavity is to be maintained, the junction between the drainage tube and the chest wall must be as airtight as possible A good junction can be made as follows

Cut some pieces of lint into discs about 4 in in diameter, with a hole in the centre of such a size that the drainage tube fits reasonably tightly These pieces of lint are soaked in melted Vaseline, which is allowed to cool on them so that they are heavily charged with it A piece of sheet tin is also wanted with a hole in the centre through which the drainage tube can pass A small wire ring is soldered on each side of this hole The method of assembling *these parts* is shown in fig 2, which represents them in diagrammatic section The tube L coming through the chest wall H passes through the lint J and then through the tin *plate K* A silkworm gut suture is tied to the loops on this plate (*k k*) and then tied firmly round the drainage tube The whole is then strapped to the chest wall with elastic strapping Gauze, wool and a manytail bandage are applied around the whole of this to absorb any leaking fluid and to keep the vaseline from soiling sheets The whole will need changing every three or four days

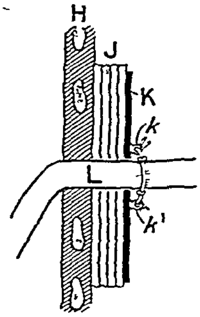

FIG 2

The degree of negative pressure can be regulated by the difference of level between the two tins When the upper tin is empty all that is necessary is to reverse the position of the tins, and to transfer the suction tube to the tin which is now uppermost It should not be necessary to do this more than once a day, and it may be that the apparatus will need no alteration for two or three days The indicator of the partial vacuum is the rubber diaphragm, which can not only be seen but felt, and it is easy for the nurse on night duty to feel whether the apparatus is working satisfactorily

THE HOSPITALS OF ROTTERDAM

THE damage done to the hospitals of Rotterdam during the German air-raids in May, 1940, is described in the *Schweizerische Medizinische Wochenschrift* for June 7 (p 724) During the methodical laying-waste of the centre of the town on May 14 the hospital at Coolsingel, after direct hits on the kitchens and engine-house, caught fire and was burnt to the ground Only a few blackened walls remain The evacuation of patients was difficult, for a church which was being used as a refuge also took fire and they had to be moved once more Dr Sekir, an assistant physician of the hospital, died from his injuries the same evening The medical library was a total loss and the town's pathology and bacteriology laboratories, which were attached to the hospital, were wiped out with all their equipment The laboratories have now found shelter in the municipal hospital at Bergweg where their directors are busy on reorganisation The famous hall where all the medical societies of Rotterdam used to meet was also destroyed The infirmary for chronic patients at Raampoortstraat was completely wiped out The ophthalmological hospital at Oostmolenwerf received a direct hit during Whitsun, but the patients and staff were able to take shelter, two days later the remains of the building and the other ophthalmological hospital in Nadorstraat were burnt down The new Zuider Hospital was taken over by the Germans on May 10 and has suffered little damage, and the hospital at Bergweg also escaped

HOW TO BE WELL FED AND PATRIOTIC

Mrs Barbara Callow's pamphlet "Good Health on War-time Food" (O U P Pp 32 6*d*), is based on talks given to working-class folk since the war broke out, and she shows understanding of their point of view and criticisms The last chapter should be read first and then again in its proper place after reading the rest of the book The only criticism is that some verbal woollinesses might be omitted Mrs Callow writes " all of us need a certain amount of body-building food every day" Surely "all of us need body-building food every day" is as true, strong, scientific and understandable But these are minor offences which need worry only the pernicketty scientist, or the paper controller, and if the booklet is read and understood and its precepts practised it should do a lot of good

FEEDING THE MULTITUDES

THE Ministry of Food have published a sixpenny pamphlet (Canteen Catering Pp 84 H M Stationery Office), as a guide to those in charge of canteens, not only as regards quantities of foods essential in making prescribed dishes but as regards the dietetic qualities of foods, dishes and menus Prof J C Drummond, in a foreword, says that "the aim in planning meals in canteens should be to provide in one meal during the day a substantial proportion of all the essential nutrients required by the body If this is ensured, the nature of the other meals becomes correspondingly less important By making good the deficiencies of the home diet, the canteen meals are of greatest benefit to the worker" If the canteen manager faithfully carries out the instructions given in the early pages of the pamphlet the feeding of the people in canteens will reach a high level It is particularly sound advice to increase the quantity of vegetables served, to give more than one vegetable in addition to potatoes, and to serve a second vegetable with fish and chips, and sausage and mashed potatoes The advice on how to introduce new and unfamiliar dishes is also good sense, if Macchiavellian The only snag is that it needs a trained dietitian to carry out the advice, and it is doubtful if there are more than 250 trained dietitians in the whole of Great Britain The training of dietitians has been more or less in abeyance since the war started and we need such for feeding the people during war-time and still more so in the subsequent peace One or two minor grumbles may be permitted What does this sentence from the foreword mean? "They [the protective foods] are called 'protective' because they are in one respect or another rich in the vitamins or other constituents vitally important for health" Are not calories and protein vitally important for health, and are white sugar and salt pork "protective foods"? On the whole the pamphlet can be strongly recommended not only to supervisors of canteens but to everyone who has to cater for large groups of people

---

MEDICAL HONOUR—The King has given permission to Flight Lieutenant W P Griffin, M B Dubl, R A F O, to wear the insignia of the order of the White Eagle, fifth class, conferred on him by the King of Jugoslavia for valuable services rendered in connexion with the war

COURSES ON WAR SURGERY—A course on war surgery of the extremities will be held at the British Postgraduate Medical School from Sept 1 to 5 A course on war surgery of the abdomen will begin on Sept 15, and a course on war medicine on Sept 29 Further information may be had from the dean of the school, Ducane Road, London, W 12

A GERMAN COUPON CONCESSION—In the *Deutsche Medizinische Wochenschrift* for July 11 (p 770) the German Food Minister announces that bread coupons marked with an R, which are intended for rye bread (Roggenerzeugnisse), may only be exchanged for white bread coupons if a medical certificate is submitted Doctors may give a certificate for this exchange to those suffering from diseases of the stomach, bowels or gall bladder, to patients who have difficulty in chewing, or to those who are hypersensitive to rye

Appointments

CRAIG, J H, M B Durh medical registrar at Royal Victoria Infirmary, Newcastle on Tyne

GAISFORD W F, M D Lond, F R C P consulting physician to the Warwickshire hospital services

HEATHER, J C, M D Lond M R C P examining factory surgeon for Coventry East

REID J L, B M Oxfd, D L O junior surgical registrar at Royal Victoria Infirmary, Newcastle on Tyne

WALDER, D N M B Brist junior surgical registrar at Royal Victoria Infirmary, Newcastle on Tyne

Colonial Service—The following appointments are announced

BLOK E A, L R C P E, assistant director of medical services, Ceylon

BOWESMAN, CHARLES M D Dubl, F R C S E, D T M & H, medical officer Gold Coast

GOSDEN, MINNIE, M B Lond, D T M & H pathologist, Sierra Leone

REID, J D, M B, D P H, D T M & H medical officer, Sierra Leone

UTTLEY, K H M D Camb, D T M & H senior medical officer, Hong Kong

Births, Marriages, and Deaths

BIRTHS

BIRD—On Aug 17, in Reading the wife of Dr J G Bird—a son

BOWLBY—On Aug 11, at Broad Chalke, Salisbury, the wife of Major John Bowlby, R A M C—a son

CURRANT—On Aug 12, at Haslemere, the wife of Dr E J Currant—a daughter

DE SWIET—On Aug 15, at Ripley Court, Surrey the wife of Dr John de Swiet—a son

FORREST HAY—On Aug 8 at Bewdley, the wife of Captain Graham Forrest Hay, R A M C—a son

HYSLOP—On Aug 14, the wife of Dr W A Hyslop of Settle, Yorks—a son

LE VAY—On Aug 15 at Oxford, the wife of Mr A D Le Vay, F R C S—a son

PRICE—On Aug 12 at Beaconsfield the wife of Major A E Kingsley Price, R A M C—a daughter

MARRIAGES

BEALES—ROSSITTER—On July 26, in London, Philip Hulme Beales, M R C S, to Valerie Maude Rossiter

FEARNLEY—ANDREWS—On Aug 16 at Graffham, Sussex, George Roche Fearnley M B to Joy Andrews

MATHISON—LEES—On July 5, at Darwen Alexander Mathison M R C S, surgeon lieutenant, R N V R, of Bedford to Betty Lees

RAWLINSON—CLAFTON—On Aug 9, in London Peter Goodwin Rawlinson M R C S, to Mary Clafton

SMYTH—RUSHTON—On Aug 12, at Claughton on Brock William Francis Smyth, M B, lieutenant, R A M C, to Phyllis Anne Rushton

YOUNG—CHURCH—On Aug 11 at Limpsfield Chart, William Brewitt Young M B, to Betty Church

DEATHS

JAMESON EVANS—On Aug 13, at Froneithyn Aberdovey John Jameson Evans, M D Birm, M B Edin, F R C S, of Edgbaston

FAWKES—On Aug 14 at Midhurst, Sussex Marmaduke Fawkes, O B E, M B Lond

1941 Students Guide 1942

THE STUDENT AND THE E M S

JOHN A RYLE, M D , F R C P
REGIUS PROFESSOR OF PHYSIC

Two years have now passed since the medical student —and this is particularly true of the student of the London schools—faced an abrupt disorganisation of his educational programme and an enforced rearrangement of his life and habits Good humoured and adaptable for the most part, the earlier days of war found him ready to accept much He grumbled probably no more and, having fewer responsibilities, possibly less than his teachers and others among the general public who stood not fearful but puzzled and anxious on the brink of our new era of world catastrophe Of one responsibility and one decision he was at once relieved for the Government decided to regard him as coming within the category of the reserved occupations Although there must have been some who found it hard to accept and a few—all honour to them—who declined to accept this preferential ruling while the rest of their generation were called upon for the hazardous tests of war, the wisdom of those who made the decision has been well supported by events Already the voracity of the armed forces for doctors and yet more doctors has seriously depleted the civilian services and seems likely before long to claim every fit medical man directly on completion of his six months' qualified apprenticeship as a house-officer

At the outbreak of war, as a new and additional service working apart from the medical services of the armed forces and yet supplying the greater part of their hospital accommodation in this country as well as the war-time needs of the civil population, the Emergency Medical Service came into being and developed simultaneously its association with the medical schools It would seem a fitting moment at the beginning of a new session and of the third year of war to consider what part this service has come to play in the life of the medical student and what contribution the medical student has already made and can continue to make to this vast service which, for all its initial difficulties and all the criticisms levelled at it has now established itself and affirmed its indispensability in our national life

* * *

In the first place the E M S operating in the London sectors made it possible for the clinical education of all the medical students of London to be maintained The parent hospitals were reduced in status and complement to casualty clearing stations in order to prepare for the air-raids which fell upon the metropolis last autumn , but the sectors, whether in county council hospitals or some of the larger mental or other special institutions taken over for the purpose supplied base hospitals wherein ward teaching could continue and where, by degrees, lectures and laboratory classes could be resumed In most sectors now there are, besides the parent hospital in town, one, two or more base hospitals in the country, and between these and the parent school the students in the clinical period are distributed Students in the preclinical period, who at first, in several instances enjoyed the hospitality of the provincial medical schools were later in some cases accommodated in country houses converted for the purpose These are situated for the most part within reasonable reach of London and the base hospitals In the parent hospitals students in their clinical period have had opportunities of seeing acute surgery and medicine and of obtaining the experience of wounds and shock and transfusion technique provided by air-raid casualties while outpatient teaching has continued without interruption Some of the L C C hospitals have been generous in affording teaching facilities to neighbouring London schools Here and at the base there have been opportunities, often better than in peace-time, of seeing a rich variety of material in institutions carrying a large quota of chronic and old-age diseases

Clinical teaching has nevertheless, suffered in many ways There has been a large exodus of members of the teaching staffs to join the medical services of the Army Navy and R A F There has been separation from libraries and laboratories and during the tenure of appointments at the base from the valuable opportunities which the outpatient clinics provide And there has been the continuing sense of unrest and uncertainty militating against reading and calculated to distract the most studious mind In other ways however clinical education has discovered unanticipated boons Thus the student in many places has found himself living at close quarters and in a more democratic association with his teachers and in friendly unofficial ways, whether in the ward or the mess acquiring information and an outlook on the problems of his chosen profession which the formal associations of the peace-time teaching round could seldom supply the value of the whole-time teacher has been made apparent in this way He has found or should have found new chances of self-instruction from hours spent on his own in wards replete with cases and physical signs of a very varied kind He has seen other types of hospital organisation and had glimpses both of the good and the bad in county or municipal administration At the base he has been able to enjoy a healthier environment and, for the most part, has not been too much disturbed by the visitations of the raiders In his London terms he has had both the surgical and the human experience of air-raid nights and the satisfaction of feeling that he was here making a definite contribution to the war effort Nor has this contribution been a mean one What some of the hospitals in heavily raided areas, often themselves the victims of high explosive and of fire would have done without the ready and willing help of students it is hard to imagine Such tasks may not profit the attainment of the examination goal but to have combined the duties of clerk and dresser with those of stretcher-bearer roof-spotter and extinguisher of incendiary bombs is indubitably to have lived and learned and to have found in emergency and risk a new return to make for the privileges of postponed military service

The teaching of pathology and bacteriology has probably suffered more than the teaching of the clinical subjects Museums class-rooms and laboratories are not easily transferred to or improvised in a county infirmary or mental institution, and a falling off in examination efficiency in the laboratory sciences is more excusable on this account By now, however arrangements should be improving and while present stability persists a steady integration of teaching with a better adaptation to its new environments should prove possible

In the early days of the war some schools favoured the principle of dispersal and scattered their students among many institutions This experiment has now been accepted as a failure and the tendency is to concentrate more and more into one or at most two country hospitals The need for a shadow hospital to which an evacuation can take place in the event of the final disruption of the home hospital by enemy action has also become apparent and the provincial medical schools, no less than the London schools, would do well to contemplate this need

* * *

We can thus say of the E M S that when all tradition seemed swept away and the cherished individualities of famous schools were wellnigh lost in the process of disbanding it provided the wherewithal of survival The student who enters the wards of the E M S hospitals on the outskirts of London in the new session will scarcely be able to visualise the discomforts and shortcomings the improvisations and sandbagging fatigues of the earlier days If he can never savour the life and provisions of his school under normal conditions he has instead a war-time tradition to make, maintain and enhance He owes a debt of gratitude to those who have, between them, prepared the way for him during the past two years Let us hope that he and they the senior students, staff, house-men, nurses medical school authorities and sector administrative officers and, above all, the evacuated patients around whom all their work is centred may come to witness an ever-improving order and prospect He should make every possible use of the human situation in which he finds himself for by so doing he will not only be storing impressions which will help him to mould his professional outlook and conduct but will also be making a real contribution to the amelioration of difficult and uncomfortable times and conditions The opportunities for technical study may have deteriorated but the opportunities for the study of mankind and for mutual instruction and assistance were probably never better

Out of new and strange discontents and new sympathies stirred by the pictures and stories of London's sick and wounded exiled from bombed streets and finding a haven in a county council hospital or its hutted annexe, it is likely that many students will extract material to set them thinking of the future of our hospital services and our medical schools Student societies should be more, rather than less, active in war-time When the time for rebuilding comes what contribution will their generation make to the permanent abolition of those slums now widely gutted and shattered, which once helped to provide so much of the disease that gave instruction to their fathers? Where and on what plan will the new hospitals and schools be built—on their own sites or in the country, like the E M S hospitals, where the restoration to health of the sick and injured is so patently expedited? Shall we perhaps maintain our enforced experiment of a city C C S and outpatient centre with a much larger unit in the country for the investigation and treatment of all but the urgent cases, and, even though nothing can condone the evils of the war, shall we be grateful none the less that it gave a final peremptory pointer for countless reforms long overdue? Will the ghost of Sir Thomas More behold at last his hospitals "in the circuite of the citie, a little without the walles so bigge, so wyde, so ample and so large, that they may seeme little townes" and "so wel appointed that though no man be sent thether against his will, yet notwithstandinge there is no sicke persone in al the citie, that had not rather lye there, then at home in his owne house" In war-time even more than in times of peace it is permissible to dream Utopian dreams if only they lead to better actions and ultimate improvement

* * *

How far have the dislocations of the war influenced the actual work and competence of the medical student? This is a hard matter to judge, but it would probably be the opinion of most teachers and examiners that academic attainment and practical efficiency have both suffered in some degree An undue dependence on the instruction of the class and the book, a shortage at times and some places of clinical and pathological material of appropriate type, the dispersal of teachers and the difficulty of concentrated study under existing conditions, particularly during the appointments held in town in the phase of heavy aerial offensive, have had effects for which strong censure would be unfair Examiners are doing their best to be considerate and yet feel it incumbent upon them to expect a reasonable and proper level of competence On those teachers who have remained with their schools and taken on whole-time service in the E M S a special responsibility falls, for they must set the standards, and with such help as their part-time colleagues, often involved in much travelling can give and the assistance of the few remaining registrars and tutors, must seek to supply deficiencies due to the loss of teaching staff and the shortcomings of institutions as a rule but ill-equipped for the advancement of learning

What are the immediate prospects of the student on qualifying? There is now no shortage of house-appointments and every man and woman must serve as a house-officer for six months before seeking duty with the armed and auxiliary forces Thereafter the choice for the men is between the Army, Navy, the Air Force and the E M S, and of these the Army is the most importunate Hitherto the E M S has been able to retain the service of a proportion of the younger men beyond the house-officer period and—since it makes hospital provision on a very large scale for the Services as well as for civilians, and its efficiency depends not a little on its junior medical officers—it would seem right that it should continue to take its quota from the medical man-power pool It could be wished that there were possibilities of interchange between the E M S and the Army The fact that so many Army doctors spend such a high proportion of their time in relative idleness tends to deter some of the young men from applying at once for commissions, but this state of affairs must be accepted as part of the inevitable wastefulness of war For the keen battalion or field ambulance medical officer there is always work to do with human interest and of high military and moral value, if only he will adapt himself to new circumstances and accept that his first duty is not now the care of "interesting cases" but the preservation of health, efficiency and morale among the fighting men

* * *

What lies ahead of us in the coming months none can say, but certainly an intensification of effort is immediately necessary in the field of medicine and medical education as it is in every other field There is still room for improvement in the mutual assistance programmes of the E M S and the medical schools We are probably in the mid-period of the war, a period when staleness and despondency sometimes begin to infiltrate men's minds The beginning of a new session, like the beginning of a new season's campaign, may well be made an occasion in the councils of the schools and in student communities for fresh resolutions and planning Could the medical student require any finer inspiration to hard and eager work than the example set him by the sailors, soldiers and airmen of his own generation and by the uncomplaining civilian sick and air-raid victims with whom and for whom in one capacity or another his turn to serve must shortly come?

DEAN AND CHAPTER

OUR thanks are due to deans and university officers and to government and municipal officials and all others who have helped us to give this account of medical education in war-time Some of what came in the post bag has gone into the orderly account of the schools Some has provided inspiration for leading articles But there are personal touches in the letters, too intimate for exact quotation or acknowledgement, of which the substance must be handed on to all who have the cause of medical education at heart The not quite verbatim passages which follow bring varying aspects of our present experiences into relief There is no drab uniformity about them, indeed they carry the seeds of hearty controversy The war, with its difficulties of transport and its blackout has shut each of us into an immediate circle and has reduced opportunities of outside intercourse It is all the more enlivening to see how experience in medical schools has varied and thus provoked the most diverse opinions

"Students from time to time criticise parts of the curriculum, but this is not a war-time peculiarity We have always invited criticism and discussion and the result, I think, is a greater understanding of difficulties and a greater degree of satisfaction on the part of students"

"It appears to me that you somewhat unduly stress the desirability of obtaining the *students'* opinion on the curriculum! In this changing world I believe that the tail will be compelled to wag the dog in order to obtain long overdue improvements in many instances, but the ordaining of the medical curriculum is not one of these"

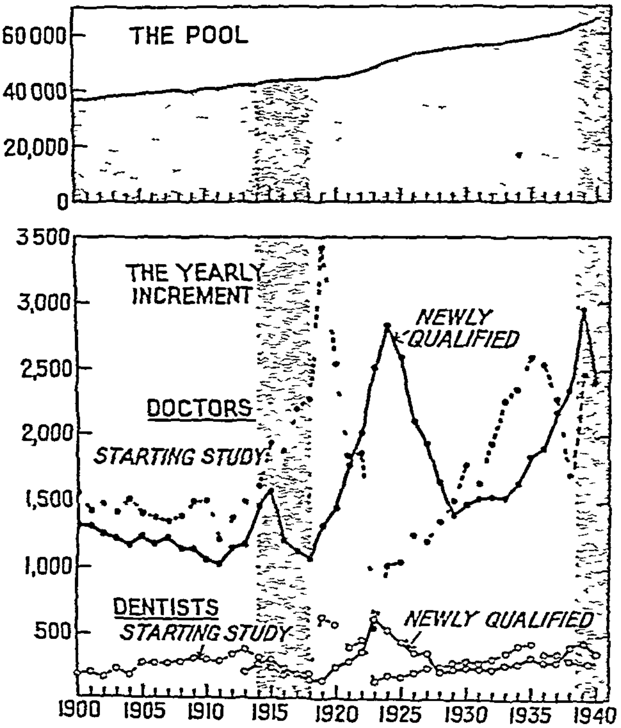
"My own personal view about the curriculum is that its chief defect lies in its (obviously impossible) attempt to make students competent in all departments of the art instead of giving them a general training so that they may turn to various forms of specialist study after graduation Our students, no doubt like others, are required to produce for the final examination certificates of instruction in 23 clinical subjects ”

“ My personal view of the new curriculum is that it lays too much stress on detail and insists too much on special courses in practically every conceivable medical subject Whereas the aim of a curriculum should be to instil a sound knowledge of the principles of medicine surgery and midwifery Once this is done all the rest can easily be added *thereto* ”

“ speeding up finds no favour with me except in abnormal circumstances It would always have been easy to compress the medical course into a shorter time by eliminating vacations , and no doubt some of your correspondents have triumphantly demonstrated this obvious truth But someone said that time is that essential which imparts strength to all things and brings them to maturity—and after all the really important part of medical education is not so much the acquisition of information, though that of course is essential, but rather the development of maturity and judgment in the individual For that time is the very essence of the matter ”

“ I do not think the time is quite ripe for detailed comments on the curriculum, which I am sure could be improved, but reform must come by collaboration between the schools and the examining bodies All educational establishments are largely in the hands of the examiners and I think I may say without undue complacency, that the present arrangements here seem to be fairly adequate for the purpose of getting students through their qualifying examinations This is not necessarily the same thing as making them good doctors but it is useless to attempt the latter without the former ”

THE NUMBERS WHO ENTER THE MEDICAL PROFESSION



“ There is one—and only one—outstanding thing that is responsible for the difficulties of medical education at the present time—the war There is also only one change that will correct matters—winning the war To suggest any change in the curriculum unless it directly increases the war effort would be to direct energy along unprofitable lines ”

“ My own personal attitude towards work outside London is one of irritation The time wasted by travelling is intolerable and opportunities to perform duties I regard as representative are greatly reduced I believe—in spite of all the smug self-satisfaction at being out of London—that the metropolis will act again as the usual magnet and gradually attract people back again to the same old conditions ”

“ You may have seen in the press that some of the hospitals have had definitely to retire into the country (Guy's, the London and St Thomas's have opened annexes) This is of the nature of an experiment, I expect, to see how it works, with a view to patients being taken into the country after the war Personally I believe it will fail The patients' friends will hate having to go into the country, and although the staff may be the present staff in the first instance, in five years time it will deteriorate unless we go in for whole-time staffs—which God forbid ! ”

“ My impression is that students are fairly well content, and this is true even of those who knew the hospital in the happy days before the war I think they realise that they are getting first hand contact with medical patients and more personal teaching and smaller classes and that there are a greater number of teachers ”

‘ Are they satisfied ? Is the modern medical student ever satisfied ? He expects far too much Not content with being in a reserved category he resents any claim upon him for defence duties although I arrange that everybody in the final year is free from anything of this kind with his energies unhandicapped But I think the trouble is *that he regards himself as a very superior* important person He reads continually of the great need for doctors in the Services, from which he concludes that his path towards speedy qualification should be made as smooth as possible, both as regards tuition and examinations ”

“ A R P A.T C S T C duties seem to have had a *beneficial effect on all* medical students who have undertaken them and great *enthusiasm* has prevailed for such work.”

“ the A.R P duties which students have willingly undertaken are a total loss from the point of view of medical education Speaking not as dean, but as M O i c of the hospital, I can only say the efficient reception and treatment of casualties would be practically impossible without the students' aid This refers to strictly non-medical duties such as fire-fighting and stretcher-bearing A certain number of students are of course employed on blood-transfusion and resuscitation teams and also as surgical dressers Here again the experience they obtain is undoubtedly beneficial to general education but practically no help in passing qualifying examinations ’

“ The councils themselves have shown the greatest willingness to coöperate on paper In practice however, almost everything depends on the existing medical superintendent If he is actively keen on teaching the students may do extremely well with the abundant clinical material at their disposal If, on the other hand, he is not actively coöperative it becomes almost impossible to organise teaching though a few students may be pertinacious or tactful enough to obtain teaching through a process of infiltration ’

REGISTRATION

No one is a *legally qualified* medical practitioner unless his name appears on the Medical Register kept by the General Council of Medical Education and Registration of the United Kingdom The Council is a standardising body ensuring that there is a definite minimum of medical education and examination requirements and it is responsible for discipline within the profession Any application to be admitted to a school of medicine on beginning the medical curriculum proper should be addressed to the dean or other appropriate authority of the school to which the applicant desires to be admitted

Students are no longer registered by the General Medical Council before their admission to schools and the number registering in the academical year 1940–41, although known to be large, was not available for insertion on the graph in the middle of this page which has been compiled from figures given in the Medical Register 1941 and Dentists Register 1941 published by Constable & Co Ltd Obviously the supply of doctors is being well maintained in comparison with the first world war provisions of his school under normal conditions he has instead a war-time tradition to make, maintain and enhance He owes a debt of gratitude to those who have, between them, prepared the way for him during the past two years Let us hope that he and they, the senior students, staff, house-men, nurses medical school authorities and sector administrative officers and, above all, the evacuated patients around whom all their work is centred may come to witness an ever-improving order and prospect He should make every possible use of the human situation in which he finds himself for by so doing he will not only be storing impressions which will help him to mould his professional outlook and conduct but will also be making a real contribution to the amelioration of difficult and uncomfortable times and conditions The opportunities for technical study may have deteriorated, but the opportunities for the study of mankind and for mutual instruction and assistance were probably never better

Out of new and strange discontents and new sympathies stirred by the pictures and stories of London's sick and wounded exiled from bombed streets and finding a haven in a county council hospital or its hutted annexe, it is likely that many students will extract material to set them thinking of the future of our hospital services *and our medical schools Student societies should be* more rather than less, active in war-time When the time for rebuilding comes, what contribution will their generation make to the permanent abolition of those slums, now widely gutted and shattered, which once helped to provide so much of the disease that gave instruction to their fathers ? Where and on what plan will the new hospitals and schools be built—on their own sites or in the country, like the E M S hospitals, where the restoration to health of the sick and injured is so patently expedited ? Shall we perhaps maintain our enforced experiment of a city C C S and outpatient centre with a much larger unit in the country for the investigation and treatment of all but the urgent cases, and, even though nothing can condone the evils of the war, shall we be grateful none the less that it gave a final peremptory pointer for countless reforms long overdue ? Will the ghost of Sir Thomas More behold at last his hospitals " in the circuite of the citie, a little without the walles so bigge, so wyde, so ample and so large, that they may seeme little townes " and " so wel appointed that though no man be sent thether against his will, yet notwithstandinge there is no sicke persone in al the citie, that had not rather lye there, then at home in his owne house " In war-time even more than in times of peace it is permissible to dream Utopian dreams if only they lead to better actions and ultimate improvement

* * *

How far have the dislocations of the war influenced the actual work and competence of the medical student ? This is a hard matter to judge but it would probably be the opinion of most teachers and examiners that academic attainment and practical efficiency have both suffered in some degree An undue dependence on the instruction of the class and the book, a shortage at times and some places of clinical and pathological material of appropriate type, the dispersal of teachers and the difficulty of concentrated study under existing conditions, particularly during the appointments held in town in the phase of heavy aerial offensive, have had effects for which strong censure would be unfair Examiners are doing their best to be considerate and yet feel it incumbent upon them to expect a reasonable and proper level of competence On those teachers who have remained with their schools and taken on whole-time *service* in the E M S *a special* responsibility falls, for they must set the standards , and with such help as their part-time colleagues, often involved in much travelling, can give and the assistance of the few remaining registrars and tutors, must seek to supply deficiencies due to the loss of teaching staff and the shortcomings of institutions as a rule but ill-equipped for the advancement of learning

What are the immediate prospects of the student on qualifying ? There is now no shortage of house-appointments and every man and woman must serve as a house-officer for six months before seeking duty with the armed and auxiliary forces Thereafter the choice for the men is between the Army, Navy, the Air Force and the E M S , and of these the Army is the most importunate Hitherto the E M S has been able to retain the [illegible] of a proportion of the younger men beyond the h[illegible] officer period and—since it makes hospital provision a very large scale for the Services as well as for [illegible] and its efficiency depends not a little on its junior medica officers—it would seem right that it should continue to take its quota from the medical man-power pool It could be wished that there were possibilities of interchange between the E M S and the Army The fact that so many Army doctors spend such a high proportion of their time in relative idleness tends to deter some of the young men from applying at once for commissions, but this state of affairs must be accepted as part of the inevitable wastefulness of war For the keen battalion or field ambulance medical officer there is always work to do with human interest and of high military and moral value, if only he will adapt himself to new circumstances and accept that his first duty is not now the care of " interesting cases " but the preservation of health, efficiency and morale among the fighting men

* * *

What lies ahead of us in the coming months none can say, but certainly an intensification of effort is immediately necessary in the field of medicine and medical *education as it is in every other field There is still room* for improvement in the mutual assistance programmes of the E M S and the medical schools We are probably in the mid-period of the war, a period when staleness and despondency sometimes begin to infiltrate men's minds The beginning of a new session, like the beginning of a new season's campaign, may well be made an occasion in the councils of the schools and in student communities for fresh resolutions and planning Could the medical student require any finer inspiration to hard and eager work than the example set him by the sailors, soldiers and airmen of his own generation and by the uncomplaining civilian sick and air-raid victims with whom and for whom in one capacity or another his turn to serve must shortly come ?

DEAN AND CHAPTER

OUR thanks are due to deans and university officers and to government and municipal officials and all others who have helped us to give this account of medical education in war-time Some of what came in the post bag has gone into the orderly account of the schools Some has provided inspiration for leading articles But there are personal touches in the letters, too intimate for exact quotation or acknowledgement, of which the substance must be handed on to all who have the cause of medical education at heart The not quite verbatim passages which follow bring varying aspects of our present experiences into relief There is no drab uniformity about them , indeed they carry the seeds of hearty controversy The war, with its difficulties of transport and its blackout has shut each of us into an immediate circle and has reduced opportunities of outside intercourse It is all the more enlivening to see how experience in medical schools has varied and thus provoked the most diverse opinions

" Students from time to time criticise parts of the curriculum, but this is not a war-time peculiarity We have always invited criticism and discussion and the result, I think, is a greater understanding of difficulties and a greater degree of satisfaction on the part of students "

" It appears to me that you somewhat unduly stress the desirability of obtaining the *students'* opinion on the curriculum ! In this changing world I believe that the tail will be compelled to wag the dog in order to obtain long overdue improvements in many instances, but the ordaining of the medical curriculum is not one of these "

" My own personal view about the curriculum is that its chief defect lies in its (obviously impossible) attempt to make students competent in all departments of the art instead of giving them a general training so that they may turn to various forms of specialist study after graduation Our students, no doubt like others, are health are suspended during the war Present regulations for medical examinations may be obtained from the Principal at Richmond College, Surrey

During the session 1940–41 the medical faculty, which is the largest in the university, contained 3605 students Thus there has been little falling off in numbers, and the Government's policy of reservation of medical students will guard against a shortage of doctors in the future The medical schools, which had returned to London last summer, have for the most part decentralised again, as the accounts of the different London teaching hospitals will show The damage to university buildings in London has of course been severe and widespread Many teachers have been released for national service but teachers in the provincial universities have pooled their services with those of London University teachers In spite of difficulties arising from dispersal of schools normal examinations have been held, and there has been no falling off in performance A board of studies in pathology, made up of all the university teachers of this subject, has been appointed Research grants have been continued as far as possible, during the year 7 medical and 17 scientific grants were awarded Examinations have been decentralised, and students have been able to take London University examinations without leaving the universities in which they are war-time guests

Student institutions have suffered in raids the boathouse has been wrecked the athletic ground bombed, some of the Union buildings gutted by fire, and Connaught Hall has had so many bombs in the neighbourhood that it has had to be closed The athletic union has ceased to act, since teams for organised games can no longer be called together, but the Tyrian club has provided athletics and cross-country running as a substitute, and of course students share in the sports of the universities of their adoption The university contingent of the O T C is still suspended, but the University Air Squadron has been revived with encouraging results

KING'S COLLEGE

At the beginning of the war the medical faculty of King's College moved from the Strand to Glasgow, but in August, 1940, it was transferred to Birmingham The faculty was too large to be housed in Bristol with the rest of the college King's medical students share the opportunities open to Birmingham medical students in the new medical school, which is one of the best equipped in the country It lies on the university campus, several miles from the city centre and on the opposite side of the city to the main industrial area Students thus live almost in the country and share a spacious students' union. Students of anatomy and physiology are instructed by their own teachers, first year students are taught in the large science department of the university of Birmingham There has been no difficulty about finding billets for them in the neighbouring district, and there has been little bomb damage in the locality and no casualties to students Birmingham is so densely populated that it has not been necessary for the students to play much part in civil defence, but they have taken their turn at fire watching in the university area For years King's College has been one of the largest medical schools in London, and has to limit the number admitted to 120 a year, the number of applications greatly exceed this

QUEEN MARY COLLEGE

London Hospital and other students can take their premedical and first M B examinations at Queen Mary College before beginning their clinical work The college has been transferred to Cambridge while the war lasts, and on the basis of two years experience there the dean reports that all is going well Students admitted have been fewer than would have been the case in London because accommodation is limited but during the last session 31 students were taking the first M B and 7 the premedical course Timetables have been arranged to allow men students to give two half-days a week to national service either in the S T C, the Home Guard or one of the other home defence bodies, and they also give up time to fire watching

UNIVERSITY COLLEGE

Raids played havoc with the fine buildings and library of University College In the medical faculty, the anatomy, physiology biochemistry and pharmaceutical departments have been transferred to Leatherhead Students working for the London first M B examination (in biology physics and chemistry) are at Bangor, where the science faculty of the college is now housed There are 60 students in each of the two years at Leatherhead, which represents a reduction of about 25% on peace-time numbers The proportion of men to women has changed slightly in favour of women Arrangements have been made so that students can serve in the Home Guard without serious interference with their studies They live close to the laboratories for the most part, and thus save time which in London would have been spent in travelling

St Bartholomew's Hospital

The medical college at Bart's is running much as it was last year Preclinical students are still happy guests at Cambridge, where it is possible to maintain the full curriculum The clinical students are working at Hill End, at the Friern Hospital and at Bart's itself Last year the London University authorities modified their regulations to allow the preclinical students to take the second M B within twelve months of the first M B, by doing a 46-week course in the year This shortened course has been given up at Bart's, however because the crowding of the work turned out to be too much for students and teachers, the ordinary terms have been resumed But during the experimental year a considerable number passed, and those who took the shortened course gained in time if not in education Clinical work has been arranged with difficulty at times Acute cases have been relatively few, partly the dean thinks, because there seems to be less acute illness about and partly because the country sector hospitals to which the medical college is attached are not allowed to admit the local acute sick these patients must go to the ordinary hospitals of their neighbourhood, not into E M S hospitals The population of London has diminished so much as a result of evacuation that the teaching hospitals are getting far fewer cases than they used to do The students, however, are well content on the whole, though they get a little tired of the increased lectures used to supplement the limited clinical material Demonstrations are given frequently on single cases, but though this method of teaching has much to recommend it, it does not provide the same experience as an opportunity to see large numbers of cases Preclinical students have joined the Home Guard Clinical students are not called upon for this service—they are already acting as fire-watchers, stretcher-bearers and first-aiders during raids These activities are sometimes exacting enough to interfere with their study

Charing Cross Hospital

In peace-time preclinical students work at King's College, but for the present they are guests of Birmingham University and have been made very welcome Fees and scholarships to the medical school are unchanged and resident appointments are the same as those available in the past except that some of the posts are at the sector hospitals instead of at Charing Cross itself

At the beginning of the war students were dispersed to hospitals in the sector and formal teaching ceased for about three weeks In January, 1940 the students were recalled to London from all the sector hospitals except one, and the school returned almost to normal But with the onset of serious raids last autumn the picture changed again The hospital was damaged though not seriously, and soon afterwards the falling off in the number of patients attending made it difficult to maintain clinical teaching at its usual standard It was then decided that Chaulden House, at Boxmoor in Hertfordshire should be bought and turned into a residential medical school This Victorian house was built by a retired whaling captain, he provided it with a farm gardens and a miniature Crystal Palace as a glasshouse Carvings of fishes and whalers inside the house sea shells decorating the stables and a tumbledown boathouse on the river carry a flavour of this nautical ghost There

Medical Schools

UNIVERSITY OF OXFORD

The Oxford medical school thanks to many generous gifts in recent years, in particular those of Lord Nuffield, is well equipped for teaching and research Before he becomes a member of the university a student has to be accepted by a college or by one of the non-collegiate bodies Next he must pass, or gain exemption from the university entrance examination responsions, in which Latin is compulsory After this he is eligible to come into residence but is not yet qualified for admission into the medical school under the new quota (64 per annum) imposed by the Government in respect of male medical students To be admitted under the quota he must satisfy the same preliminary requirements as are now in force for the final honour school of animal physiology In the ordinary case, this means that he must pass certain preliminary examinations in natural science These are subject 4 (biology) and either subjects 2 and 3 (mechanics and physics chemistry) or else subject 5 (physics and chemistry) as the higher standard Most students take these subjects before coming up to the university and begin to work on anatomy and physiology during their first university year They are thus able to take organic chemistry at the end of their first term and thereafter to prepare for the examinations in human anatomy and physiology for the first B M , these they can take in their fifth or sixth term No-one can take the B M , B Ch degree unless he has first taken a B A degree In peace-time most medical students obtain their B A degrees by specialising for a year in work for the final honour school of animal physiology During the war, however a pass B A degree is being awarded on the results of the first B M and the honours examination is being taken only by those whose tutors specially recommend them there will be about ten of these in the coming session After passing the first B M —usually at the end of his second year—the student who is not taking the honours degree prepares for the second B M in which the subjects are at present pharmacology and principles of therapeutics, general pathology and bacteriology, forensic medicine and public health, special pathology medicine surgery and midwifery The examinations in the four first subjects mentioned can be taken separately but a student must pass simultaneously in the last three Unless the candidate is already a registered medical practitioner the examination in the final three may not be taken until the fifteenth term from university matriculation , this is a concession from the eighteen terms required in peace-time Normally, after passing the first B M , students continue their training at one of the London or provincial teaching hospitals, but since war broke out limited numbers have been given the opportunity to take the whole medical course in Oxford The qualifying degrees of B M , B Ch are a necessary preliminary to the degrees of Doctor of Medicine (D M) or Master of Surgery (M Ch) To obtain a D M degree a candidate must present a thesis and get it approved by the Board of the Faculty of Medicine , the degree of M Ch is conferred on the result of an examination The university offers a diploma in ophthalmology Details about the preclinical courses and the D O course may be obtained from the Dean of the Medical School University Museum, Oxford, and about the clinical courses from the Clinical Sub-Dean, Radcliffe Infirmary Oxford

Students who do their whole medical course in Oxford receive their clinical training at the Radcliffe Infirmary, where teaching is given by the honorary staff of the infirmary, the Nuffield professors and their assistants and others About 150 students are doing different parts of their clinical work at the infirmary, where before the war about a dozen students were taking an introductory course lasting six months There have been difficulties, of course, about grafting a relatively large school on a busy hospital not accustomed to much teaching, but they have been overcome On the whole students are well satisfied, and the absence of raids has made things easier for them and for their teachers They are not required to belong to the S T C but have undertaken A R P work in connexion with the hospital

UNIVERSITY OF CAMBRIDGE

Men are admitted to the university when they have been accepted as members of a college or approved foundation and after passing the college entrance examination and the previous examination or its equivalent Women are not admitted to membership of the university, but they are instructed and examined by the university and may receive any of the degrees and diplomas open to men Most colleges require students to have passed or gained exemption from three or more parts of the first M B examination In normal times an undergraduate would be expected to take honours in a tripos at the end of three years, but the university has suspended this regulation as an emergency measure and permits him to take his B A degree on passing the second, or qualifying examination, provided he has completed nine terms of residence At present, attendance at certain courses of clinical instruction away from Cambridge will be recognised in lieu of terms of residence and will excuse some of the requirements for the B A degree The subjects studied are, as elsewhere, physics, chemistry and biology for the first M B and anatomy, physiology and pharmacology for the qualifying examination , the final examination for the degree of M B B Chir is taken after two years and nine months clinical instruction at one of the teaching hospitals, the subjects being surgery, midwifery and gynæcology physic pathology and pharmacology Some clinical instruction to senior students is given at Addenbrooke's Hospital before they take the qualifying examination

The university offers an M D to graduates who take a further examination and present a thesis The M Chir degree is given on results of an examination The university offers a diploma in medical radiology and electrology but this is likely to be suspended next year Particulars of the regulations may be obtained from the Registrary the Registry, Cambridge

Though the obligation to take the honours tripos has been suspended, many students have preferred to work for it as usual , no less than 130 took the first part of it in May and more than 120 were classed in the tripos last year The demands of the Services have greatly reduced the teaching staff , the numbers of students have been large but it has been possible to carry on with all the lectures and practical classes for men preparing for the tripos

UNIVERSITY OF LONDON

There have been no drastic changes in the regulations or training in the university since the outbreak of war In order to encourage students to qualify as early as possible, an extra M B examination has been arranged for December of this year Students are received by the university after passing matriculation, and become members of one of the thirteen recognised medical schools attached to the teaching hospitals Students of Charing Cross, King's, St George's and Westminster usually do their preclinical work at King's College London Hospital students can attend Queen Mary College for their preliminary work and most University College Hospital students begin their course at University College For the M B B S degree the student must pass a first examination in the usual premedical subjects, a second examination in anatomy and physiology (including organic chemistry, biochemistry and pharmacology) and finals in medicine, surgery, obstetrics and gynæcology, pathology, hygiene, forensic medicine, and applied pharmacology and therapeutics

The university also confers degrees on external students who have passed or been exempted from matriculation not less than 5½ years before, who have passed subsequent examinations equivalent to those passed by an internal student and who have been working for 4½ years since passing the premedical examination at one or more of the medical schools recognised by the university for the purpose , one year at least must have been spent in a school in the United Kingdom

The M D degree is given to medical graduates who pass an examination and the M S is also given on the result of an examination The university offers diplomas in bacteriology, clinical pathology, dietetics, medical radiology, and public health, and an academic diploma in psychology , the courses in bacteriology and public health are suspended during the war Present regulations for medical examinations may be obtained from the Principal at Richmond College Surrey

During the session 1940–41 the medical faculty which is the largest in the university contained 3605 students Thus there has been little falling off in numbers and the Government's policy of reservation of medical students will guard against a shortage of doctors in the future The medical schools which had returned to London last summer have for the most part decentralised again as the accounts of the different London teaching hospitals will show The damage to university buildings in London has of course been severe and widespread Many teachers have been released for national service but teachers in the provincial universities have pooled their services with those of London University teachers In spite of difficulties arising from dispersal of schools normal examinations have been held and there has been no falling off in performance A board of studies in pathology made up of all the university teachers of this subject has been appointed Research grants have been continued as far as possible during the year 7 medical and 17 scientific grants were awarded Examinations have been decentralised and students have been able to take London University examinations without leaving the universities in which they are war-time guests

Student institutions have suffered in raids the boat-house has been wrecked the athletic ground bombed, some of the Union buildings gutted by fire and Connaught Hall has had so many bombs in the neighbourhood that it has had to be closed The athletic union has ceased to act since teams for organised games can no longer be called together but the Tyrian club has provided athletics and cross-country running as a substitute and of course students share in the sports of the universities of their adoption The university contingent of the O T C is still suspended but the University Air Squadron has been revived with encouraging results

KING'S COLLEGE

At the beginning of the war the medical faculty of King's College moved from the Strand to Glasgow but in August 1940 it was transferred to Birmingham The faculty was too large to be housed in Bristol with the rest of the college King's medical students share the opportunities open to Birmingham medical students in the new medical school which is one of the best equipped in the country It lies on the university campus several miles from the city centre and on the opposite side of the city to the main industrial area Students thus live almost in the country and share a spacious students' union. Students of anatomy and physiology are instructed by their own teachers first year students are taught in the large science department of the university of Birmingham There has been no difficulty about finding billets for them in the neighbouring district and there has been little bomb damage in the locality and no casualties to students Birmingham is so densely populated that it has not been necessary for the students to play much part in civil defence but they have taken their turn at fire watching in the university area For years King's College has been one of the largest medical schools in London and has to limit the number admitted to 120 a year the number of applications greatly exceed this

QUEEN MARY COLLEGE

London Hospital and other students can take their premedical and first M B examinations at Queen Mary College before beginning their clinical work The college has been transferred to Cambridge while the war lasts and on the basis of two years experience there the dean reports that all is going well Students admitted have been fewer than would have been the case in London because accommodation is limited but during the last session 31 students were taking the first M B and 7 the premedical course Timetables have been arranged to allow men students to give two half-days a week to national service either in the S T C, the Home Guard or one of the other home defence bodies and they also give up time to fire watching

UNIVERSITY COLLEGE

Raids played havoc with the fine buildings and library of University College In the medical faculty the anatomy physiology biochemistry and pharmaceutical departments have been transferred to Leatherhead Students working for the London first M B examination (in biology physics and chemistry) are at Bangor where the science faculty of the college is now housed There are 60 students in each of the two years at Leatherhead which represents a reduction of about 25% on peace-time numbers The proportion of men to women has changed slightly in favour of women Arrangements have been made so that students can serve in the Home Guard without serious interference with their studies They live close to the laboratories for the most part and thus save time which in London would have been spent in travelling

St Bartholomew's Hospital

The medical college at Bart's is running much as it was last year Preclinical students are still happy guests at Cambridge where it is possible to maintain the full curriculum The clinical students are working at Hill End at the Friern Hospital and at Bart's itself Last year the London University authorities modified their regulations to allow the preclinical students to take the second M B within twelve months of the first M B, by doing a 46-week course in the year This shortened course has been given up at Bart's however because the crowding of the work turned out to be too much for students and teachers the ordinary terms have been resumed But during the experimental year a considerable number passed and those who took the shortened course gained in time if not in education Clinical work has been arranged with difficulty at times Acute cases have been relatively few partly the dean thinks because there seems to be less acute illness about and partly because the country sector hospitals to which the medical college is attached are not allowed to admit the local acute sick these patients must go to the ordinary hospitals of their neighbourhood not into E M S hospitals The population of London has diminished so much as a result of evacuation that the teaching hospitals are getting far fewer cases than they used to do The students however are well content on the whole though they get a little tired of the increased lectures used to supplement the limited clinical material Demonstrations are given frequently on single cases, but though this method of teaching has much to recommend it it does not provide the same experience as an opportunity to see large numbers of cases Preclinical students have joined the Home Guard Clinical students are not called upon for this service—they are already acting as fire-watchers stretcher-bearers and first-aiders during raids These activities are sometimes exacting enough to interfere with their study

Medical Schools

UNIVERSITY OF OXFORD

The Oxford medical school thanks to many generous gifts in recent years, in particular those of Lord Nuffield, is well equipped for teaching and research Before he becomes a member of the university a student has to be accepted by a college or by one of the non-collegiate bodies Next he must pass, or gain exemption from, the university entrance examination responsions, in which Latin is compulsory After this he is eligible to come into residence but is not yet qualified for admission into the medical school under the new quota (64 per annum) imposed by the Government in respect of male medical students To be admitted under the quota he must satisfy the same preliminary requirements as are now in force for the final honour school of animal physiology In the ordinary case, this means that he must pass certain preliminary examinations in natural science These are subject 4 (biology) and either subjects 2 and 3 (mechanics and physics, chemistry) or else subject 5 (physics and chemistry) as the higher standard Most students take these subjects before coming up to the university and begin to work on anatomy and physiology during their first university year They are thus able to take organic chemistry at the end of their first term and thereafter to prepare for the examinations in human anatomy and physiology for the first B M these they can take in their fifth or sixth term No-one can take the B M , B Ch degree unless he has first taken a B A degree In peace-time most medical students obtain their B A degrees by specialising for a year in work for the final honour school of animal physiology During the war, however a pass B A degree is being awarded on the results of the first B M , and the honours examination is being taken only by those whose tutors specially recommend them there will be about ten of these in the coming session After passing the first B M —usually at the end of his second year—the student who is not taking the honours degree prepares for the second B M in which the subjects are at present pharmacology and principles of therapeutics, general pathology and bacteriology, forensic medicine and public health, special pathology medicine, surgery and midwifery The examinations in the four first subjects mentioned can be taken separately but a student must pass simultaneously in the last three Unless the candidate is already a registered medical practitioner the examination in the final three may not be taken until the fifteenth term from university matriculation , this is a concession from the eighteen terms required in peace-time Normally, after passing the first B M , students continue their training at one of the London or provincial teaching hospitals, but since war broke out limited numbers have been given the opportunity to take the whole medical course in Oxford The qualifying degrees of B M , B Ch are a necessary preliminary to the degrees of Doctor of Medicine (D M) or Master of Surgery (M Ch) To obtain a D M degree a candidate must present a thesis and get it approved by the Board of the Faculty of Medicine , the degree of M Ch is conferred on the result of an examination The university offers a diploma in ophthalmology Details about the preclinical courses and the D O course may be obtained from the Dean of the Medical School University Museum, Oxford, and about the clinical courses from the Clinical Sub-Dean, Radcliffe Infirmary, Oxford

Students who do their whole medical course in Oxford receive their clinical training at the Radcliffe Infirmary, where teaching is given by the honorary staff of the infirmary, the Nuffield professors and their assistants and others About 150 students are doing different parts of their clinical work at the infirmary, where before the war about a dozen students were taking an introductory course lasting six months There have been difficulties, of course, about grafting a relatively large school on a busy hospital not accustomed to much teaching, but they have been overcome On the whole students are well satisfied and the absence of raids has made things easier for them and for their teachers They are not required to belong to the S T C but have undertaken A R P work in connexion with the hospital

UNIVERSITY OF CAMBRIDGE

Men are admitted to the university when they have been accepted as members of a college or approved foundation and after passing the college entrance examination and the previous examination or its equivalent Women are not admitted to membership of the university, but they are instructed and examined by the university and may receive any of the degrees and diplomas open to men Most colleges require students to have passed or gained exemption from three or more parts of the first M B examination In normal times an undergraduate would be expected to take honours in a tripos at the end of three years, but the university has suspended this regulation as an emergency measure and permits him to take his B A degree on passing the second, or qualifying examination, provided he has completed nine terms of residence At present, attendance at certain courses of clinical instruction away from Cambridge will be recognised in lieu of terms of residence and will excuse some of the requirements for the B A degree The subjects studied are, as elsewhere, physics, chemistry and biology for the first M B and anatomy, physiology and pharmacology for the qualifying examination , the final examination for the degree of M B B Chir is taken after two years and nine months clinical instruction at one of the teaching hospitals, the subjects being surgery, midwifery and gynæcology physic pathology and pharmacology Some clinical instruction to senior students is given at Addenbrooke's Hospital before they take the qualifying examination

The university offers an M D to graduates who take a further examination and present a thesis The M Chir degree is given on results of an examination The university offers a diploma in medical radiology and electrology but this is likely to be suspended next year Particulars of the regulations may be obtained from the Registrary the Registry, Cambridge

Though the obligation to take the honours tripos has been suspended, many students have preferred to work for it as usual , no less than 130 took the first part of it in May, and more than 120 were classed in the tripos last year The demands of the Services have greatly reduced the teaching staff , the numbers of students have been large, but it has been possible to carry on with all the lectures and practical classes for men preparing for the tripos

UNIVERSITY OF LONDON

There have been no drastic changes in the regulations or training in the university since the outbreak of war In order to encourage students to qualify as early as possible, an extra M B examination has been arranged for December of this year Students are received by the university after passing matriculation, and become members of one of the thirteen recognised medical schools attached to the teaching hospitals Students of Charing Cross, King's, St George's and Westminster usually do their preclinical work at King's College London Hospital students can attend Queen Mary College for their preliminary work and most University College Hospital students begin their course at University College For the M B B S degree the student must pass a first examination in the usual premedical subjects, a second examination in anatomy and physiology (including organic chemistry, biochemistry and pharmacology) and finals in medicine, surgery, obstetrics and gynæcology, pathology, hygiene, forensic medicine, and applied pharmacology and therapeutics

The university also confers degrees on external students who have passed or been exempted from matriculation not less than 5½ years before, who have passed subsequent examinations equivalent to those passed by an internal student and who have been working for 4½ years since passing the premedical examination at one or more of the medical schools recognised by the university for the purpose , one year at least must have been spent in a school in the United Kingdom

The M D degree is given to medical graduates who pass an examination and the M S is also given on the result of an examination The university offers diplomas in bacteriology, clinical pathology, dietetics, medical radiology, and public health, and an academic diploma in psychology , the courses in bacteriology and public cology of the school were also removed to Cambridge at the beginning of the war with their professorial staffs Courses for the primary fellowship are held in Cambridge twice a year in conjunction with the medical school of St Bartholomew's Hospital Junior clinical students are sent first to Chase Farm E M S Hospital at Enfield, or to St Andrew's Hospital Billericay, near the annexe at Brentwood After six or nine months in the wards under London Hospital teachers, they take a pathology course at Chase Farm, and then go on either to the Brentwood annexe or to the North Middlesex County Hospital at Edmonton, which has a thousand beds After a period as student house-officers or E M S dressers at sector hospitals they return to the London, or to one of the neighbouring L C C hospitals as senior students to prepare for finals During this period they live free of charge in the hospital to which they are attached as emergency dressers, and come to the London for lectures and clinical teaching in the wards and outpatient departments Students in the clinical years are excused from civil defence duties , during an emergency their services are needed in the hospital itself

St Mary's Hospital

The action of the Government in restricting the entry at all medical schools to a figure representing the average entry of the last three years will not affect St Mary's There the entry has been restricted for some years to preserve a constant ratio between number of beds and number of students During the past year 68 students preclinical and clinical were admitted and 430 were in training Fees and scholarships are unchanged Students in the clinical years are taught in London at St Mary's and at three large London County Council hospitals, two of which are in the neighbourhood of St Mary's They are also taught at Harefield, a Middlesex County hospital with 1000 beds, 16 miles from London and staffed by St Mary's, which represents a second St Mary's outside London Students live at all five hospitals, and have access to a much larger number of beds than they do in peace-time They all work at St Mary's for some part of their training and take their pathology course there The contact between students and members of the honorary staff has been much more intimate than in the past , five of the staff live in St Mary's and at Harefield several others are living close to the doors of the hospital Students thus see more of their teachers and this innovation—perhaps the only change of moment in medical education during the war years—has probably come to stay The small number of students at each hospital has made the association with teachers even closer

Before the war there were 31 resident posts available , now, 101 appointments are made annually by St Mary's at the various hospitals of the sector The holders work under members of the St Mary's honorary staff, and every man who applies can now get a resident appointment St Mary's itself, the medical school and the sports ground at Teddington have so far been undamaged by the war The medical society and other student activities are going on as usual, and the rugby football club has had a successful season The disadvantages of dispersal have, on the whole, been counterbalanced by the gains

Middlesex Hospital

The school has been able to meet the demands of war without too much disorganisation The preclinical students are guests of the medical school of Leeds University, where by courtesy of the Vice-Chancellor they are taught by their own professors for the London degree in medicine and for the examinations of the Conjoint Board At present some of the clinical students are distributed in the three sector hospitals, Tindal House at Aylesbury, Mount Vernon at Northwood and the Central Middlesex at Willesden, but the greater part of them are at the Middlesex itself There are ample patients in the sector hospitals, and the students are moved between them according to the stage reached in their studies Arrangements have lately been made for some students to receive instruction at the Royal Hospital, Wolverhampton, where there is abundant clinical material , students are grateful to the Royal Hospital staff for their tuition and interest

Royal Free Hospital

The London School of Medicine is open only to women Fees and resident appointments have not been affected by the war and additional house posts are available at the sector hospitals The preclinical students of all three years are now working at University College of the South West, Exeter, and though they are suffering from lack of contact with the more senior years they are finding compensations The clinical students are getting good and varied experience acting as clerks and dressers for periods of three months at a time in the sector hospitals They work at the E M S hospital at Arlesey, at Oster House St Albans and at Wellhouse Hospital Barnet, in addition to the Royal Free itself Their midwifery experience is gained at Shardeloes, Amersham, at the Mothers' Hospital Clapton, and at Exeter The scattering of students in several centres is bound to loosen the corporate bond of the school to some extent, but the varied clinical material has given the students insight into a wide range of conditions

St Thomas's Hospital

St Thomas's suffered early, severely and repeatedly during the air attacks on London In April of this year its new " home in the country " was opened in Surrey, in a hutted hospital originally built for the military authorities The full complement of beds here will be 360 , it is equipped with laboratories and X-ray department, and an ambulance service has been arranged to bring patients down from London Members of the honorary staff who are not in the Services have beds there for their patients, and the usual staff of housemen and registrars have been appointed Batches of clerks and dressers come down to do their medical and surgical appointments in rotation, but the main hospital in London is still able to undertake outpatient teaching, and two wards are being maintained there for civilian acute cases and air-raid casualties , there is also a small but active obstetrical unit Premedical and preclinical students are working at Godalming and have settled down remarkably well there A residential hostel has brought them into happy personal contact with their teachers The clinical course has necessarily altered its shape, but with special tutors and closer supervision of individual students, elementary grounding and instruction in clinical medicine has probably been bettered Outpatient teaching, and teaching in the special departments, has inevitably suffered a little The students appreciate the privilege of belonging to a reserved occupation, and work harder than they did in peace-time All premedical and preclinical students are required to join a national service unit but clinical students working for short periods at different centres, cannot easily do this

University College Hospital

Since last year a medical school has been established at Stanboroughs Hydro, near Watford where systematic teaching is given in medicine and surgery The annexe houses the museum library, lecture-room, bacteriological laboratories and restaurant and rooms have also been assigned to the students' medical society and the women's common room club Sixty students are quartered in the building An introductory course in junior clinical medicine surgery and pathology is held at the beginning of the winter and summer sessions, and at the end of this course students begin their clerking and dressing appointments which cover a period of twelve months. Clinical teaching is carried out partly at Leavesden Emergency Hospital which is close to the medical school, and partly in Stanboroughs Hydro itself While working at Leavesden some students live in a nearby villa which serves as a hostel and has been provided with a library, museum, recreation-room and canteen Every student is seconded to University College Hospital for two periods of about three weeks each, to help in the emergency medical scheme and to act as dresser in the treatment of air-raid casualties Experience in medical, surgical and gynæcological outpatient departments is gained at Watford Peace Memorial Hospital, where members of University College Hospital staff hold clinics are quarters here for sixty students, who sleep in dormitories warmed by gas fires and share the living-rooms, lecture-rooms, tennis-courts, playing-field and domestic service. To limit the financial burden on parents at this time the school is bearing all overhead charges, which makes it possible to give accommodation and board to students at 35s. a week. Outbuildings have been converted into a pathological laboratory 45 feet long; this has been well equipped from the parent hospital, and the museum specimens have also been brought down. The library is housed in the "silence room," which is also used for lectures, and the epidiascope has its place in the games room, which offers other attractions in the form of table-tennis, darts and a piano. Students do their clinical work at Ashridge and at Stanmore Royal National Orthopædic Hospital, to which they are taken by a motor coach of character. Enthusiasm for gardening is evident among Chaulden residents, especially for raising vegetables. They have an active Home Guard section which is attached to the local contingent. At Stanmore they get medical, surgical, orthopædic, gynæcological and special experience in abundance, but feel the lack of outpatients. The Cambridge University Medical Society's analysis shows, however, that with access to 3000 beds students at Charing Cross are getting wider experience than students of any other metropolitan teaching hospital except the London.

St. George's Hospital

St. George's takes about a hundred students, all men. The sector to which it belongs is not perhaps as happily placed as some, because there is no large outlying hospital which could be taken over and staffed for teaching, with adequate grouping of patients and students. One of the sector hospitals is under the control of the local authority and the others are hutted hospitals built by the Ministry of Health and attached to the local public assistance institutions. Thus it has not been easy to control the training of students transferred to them. Dispersal of students to these hospitals became necessary last September, and in spite of lack of suitable cases for teaching, and lack of teachers—since more than half the staff have joined the forces—medical education has been maintained at something like its peace-time level. The hospital is planning, however, to open a country branch of 150 beds of its own within twenty miles of London, where it is proposed to equip a large private house and grounds as a medical school. Students will thus be centralised in excellent surroundings. The bulk of bedside teaching and laboratory work will be done at this branch, which is close enough to London for students to attend the flourishing outpatient department at the parent hospital. Some students, mainly seniors, will have to remain in London to assist in treatment of casualties. A.R.P. duties undertaken by the students have contributed little to their medical education, but the efficient reception and treatment of casualties would hardly have been possible if the students had not undertaken the accessory duties of stretcher-bearing and fire-fighting. Students are also attached to the blood transfusion, resuscitation and surgical teams, where the experience they gain is undoubtedly valuable, but of little help to them in passing examinations.

Guy's Hospital

Students in the preclinical years are still working at Tunbridge Wells near the sector hospital of Pembury. Four large buildings have been equipped and furnished, some as lecture-rooms and laboratories and others as hostels with accommodation for about 300 students. The remaining students are living in lodgings in the district. The largest of the four buildings, Sherwood Park, about a mile and a half from the town, contains the chemistry laboratories and dissecting-rooms, lecture-rooms, dining, reading and common rooms and the offices of the dean. The physiology department is in another of the houses and the biochemistry and physics department in a third; since last year the physics department has been moved to roomier quarters in a neighbouring building. Teachers and students have been brought into closer contact. Athletic facilities are available for rugger, swimming, golf, tennis, squash and even rowing on the Medway. Students in the clinical years are working either at Guy's itself, which has been able to carry on in spite of serious damage, or at the sector hospitals at Farnborough, Pembury and Orpington. At Guy's, ward rounds, outpatients and courses of lectures are being conducted as in peace-time. The number of beds available for teaching has, of course, been reduced, but their loss has been more than balanced by the number of beds available in the sector hospitals, and recently a country branch of the hospital has been opened in the Wildernesse, a country club, at Seal, near Sevenoaks. This is to be called Guy's U.S.A. Hospital because the Hollywood branch of the "Bundles for Britain" organisation is taking a keen interest in it, and is providing much valuable equipment. This new annexe contains about 110 beds, but is unfortunately too small to house any part of the medical school. Teaching rounds are being held there, however, so that it is playing some part in medical education. At Farnborough and Pembury the teaching is undertaken by members of Guy's staff who are living there. After a preliminary period at Pembury, clinical students go to the sector hospitals to begin their appointments as clerks and dressers. After that they return to Guy's for the remainder of their training, with the exception of the obstetric course which is taken either at Farnborough or Pembury where there are large maternity wards. During the past year the examinations for entrance scholarships and most of the prize examinations have been conducted as usual. At present all students qualifying can take appointments as resident officers at Guy's or in various hospitals in the sector.

King's College Hospital

The medical school has now settled down, in so far as that is possible at present. Some students do their preclinical work at King's College (now a guest at Birmingham), others come from Oxford or Cambridge. In peace-time students are only admitted twice a year, but at present they are being admitted as soon as they pass their second M.B. examination. Newcomers to clinical work go at once to Horton Emergency Hospital at Epsom, where they are either housed in the hospital or billeted in the town. During the first three months they take an elementary course in clinical medicine and surgery and a full course in pathology in the laboratories of Epsom College. They spend their second six months at the Blind School Emergency Hospital, at Leatherhead, attached to medical and surgical firms, and during this period they are seconded for a fortnight to King's College Hospital and Croydon General for experience in casualty dressing. At the end of the six months at Leatherhead students return to Horton and continue as ward clerks and dressers for another year. They are attached to various firms for four months at a time. The firms are mixed, each having a physician, a general surgeon and a special surgeon attached to it. In addition to clinical work the students get their anæsthetic experience during this year. Towards the end of it they are seconded in groups to Cuckfield, where they see practice in children's diseases, and to Hayward's Heath Emergency Hospital for study of nervous diseases. They get their obstetric experience, both hospital and district, at the Mayday Hospital, Croydon, and return for their final period to King's College Hospital, where they live in, attend the outpatient department, and assist in the resuscitation room and the wards when air-raid casualties are admitted.

London Hospital

Students can come to the hospital direct, or from one of the universities. The London is responsible for Sectors I and II; it has escaped serious damage and remains the headquarters of the medical school. The beds have been reduced from the pre-war figure of 900 to 350. An annexe has been opened at Brentwood with 360 beds. The organisation of the E.M.S. at the beginning of the war brought the medical school into relation with all the hospitals in Essex and many in London, Middlesex and Hertfordshire. The clinical facilities of the school have thus been greatly extended by the war. Chemistry, physics and biology are taught at Queen Mary College, now transferred to Cambridge. The department of anatomy, physiology and pharmacology of the school were also removed to Cambridge at the beginning of the war with their professorial staffs. Courses for the primary fellowship are held in Cambridge twice a year in conjunction with the medical school of St Bartholomew's Hospital. Junior clinical students are sent first to Chase Farm E.M.S. Hospital at Enfield or to St Andrew's Hospital, Billericay, near the annexe at Brentwood. After six or nine months in the wards under London Hospital teachers they take a pathology course at Chase Farm and then go on either to the Brentwood annexe or to the North Middlesex County Hospital at Edmonton, which has a thousand beds. After a period as student house-officers or E.M.S. dressers at sector hospitals they return to the London or to one of the neighbouring L.C.C. hospitals as senior students to prepare for finals. During this period they live free of charge in the hospital to which they are attached as emergency dressers and come to the London for lectures and clinical teaching in the wards and out-patient departments. Students in the clinical years are excused from civil defence duties; during an emergency their services are needed in the hospital itself.

St. Mary's Hospital

The action of the Government in restricting the entry at all medical schools to a figure representing the average entry of the last three years will not affect St. Mary's. There the entry has been restricted for some years to preserve a constant ratio between number of beds and number of students. During the past year 68 students, preclinical and clinical, were admitted and 430 were in training. Fees and scholarships are unchanged. Students in the clinical years are taught in London at St. Mary's and at three large London County Council hospitals, two of which are in the neighbourhood of St. Mary's. They are also taught at Harefield, a Middlesex County hospital with 1000 beds 16 miles from London and staffed by St. Mary's, which represents a second St. Mary's outside London. Students live at all five hospitals and have access to a much larger number of beds than they do in peace-time. They all work at St. Mary's for some part of their training and take their pathology course there. The contact between students and members of the honorary staff has been much more intimate than in the past: five of the staff live in St. Mary's and at Harefield several others are living close to the doors of the hospital. Students thus see more of their teachers, and this innovation—perhaps the only change of moment in medical education during the war years—has probably come to stay. The small number of students at each hospital has made the association with teachers even closer.

Before the war there were 31 resident posts available; now 101 appointments are made annually by St. Mary's at the various hospitals of the sector. The holders work under members of the St. Mary's honorary staff and every man who applies can now get a resident appointment. St. Mary's itself, the medical school and the sports ground at Teddington have so far been undamaged by the war. The medical society and other student activities are going on as usual, and the rugby football club has had a successful season. The disadvantages of dispersal have, on the whole, been counterbalanced by the gains.

Middlesex Hospital

The school has been able to meet the demands of war without too much disorganisation. The preclinical students are guests of the medical school of Leeds University, where by courtesy of the Vice-Chancellor they are taught by their own professors for the London degree in medicine and for the examinations of the Conjoint Board. At present some of the clinical students are distributed in the three sector hospitals, Tindal House at Aylesbury, Mount Vernon at Northwood and the Central Middlesex at Willesden, but the greater part of them are at the Middlesex itself. There are ample patients in the sector hospitals and the students are moved between them according to the stage reached in their studies. Arrangements have lately been made for some students to receive instruction at the Royal Hospital, Wolverhampton, where there is abundant clinical material; students are grateful to the Royal Hospital staff for their tuition and interest.

Royal Free Hospital

The London School of Medicine is open only to women. Fees and resident appointments have not been affected by the war and additional house posts are available at the sector hospitals. The preclinical students of all three years are now working at University College of the South West, Exeter, and though they are suffering from lack of contact with the more senior years they are finding compensations. The clinical students are getting good and varied experience, acting as clerks and dressers for periods of three months at a time in the sector hospitals. They work at the E.M.S. hospital at Arlesey, at Oster House, St. Albans, and at Wellhouse Hospital, Barnet, in addition to the Royal Free itself. Their midwifery experience is gained at Shardeloes, Amersham, at the Mothers' Hospital, Clapton, and at Exeter. The scattering of students in several centres is bound to loosen the corporate bond of the school to some extent, but the varied clinical material has given the students insight into a wide range of conditions.

St. Thomas's Hospital

St. Thomas's suffered early, severely and repeatedly during the air attacks on London. In April of this year its new "home in the country" was opened in Surrey in a hutted hospital originally built for the military authorities. The full complement of beds here will be 360; it is equipped with laboratories and X-ray department, and an ambulance service has been arranged to bring patients down from London. Members of the honorary staff who are not in the Services have beds there for their patients, and the usual staff of housemen and registrars have been appointed. Batches of clerks and dressers come down to do their medical and surgical appointments in rotation, but the main hospital in London is still able to undertake outpatient teaching, and two wards are being maintained there for civilian acute cases and air-raid casualties; there is also a small but active obstetrical unit. Premedical and preclinical students are working at Godalming and have settled down remarkably well there. A residential hostel has brought them into happy personal contact with their teachers. The clinical course has necessarily altered its shape, but with special tutors and closer supervision of individual students elementary grounding and instruction in clinical medicine has probably been bettered. Outpatient teaching and teaching in the special departments has inevitably suffered a little. The students appreciate the privilege of belonging to a reserved occupation, and work harder than they did in peace-time. All premedical and preclinical students are required to join a national service unit, but clinical students, working for short periods at different centres, cannot easily do this.

University College Hospital

Since last year a medical school has been established at Stanboroughs Hydro, near Watford, where systematic teaching is given in medicine and surgery. The annexe houses the museum, library, lecture-room, bacteriological laboratories and restaurant, and rooms have also been assigned to the students' medical society and the women's common room club. Sixty students are quartered in the building. An introductory course in junior clinical medicine, surgery and pathology is held at the beginning of the winter and summer sessions and at the end of this course students begin their clerking and dressing appointments which cover a period of twelve months. Clinical teaching is carried out partly at Leavesden Emergency Hospital which is close to the medical school, and partly in Stanboroughs Hydro itself. While working at Leavesden some students live in a nearby villa which serves as a hostel and has been provided with a library, museum, recreation-room and canteen. Every student is seconded to University College Hospital for two periods of about three weeks each, to help in the emergency medical scheme and to act as dresser in the treatment of air-raid casualties. Experience in medical, surgical and gynæcological out-patient departments is gained at Watford Peace Memorial Hospital, where members of University College Hospital staff hold clinics.

are quarters here for sixty students, who sleep in dormitories warmed by gas fires and share the living-rooms, lecture-rooms, tennis-courts, playing-field and domestic service To limit the financial burden on parents at this time the school is bearing all overhead charges, which makes it possible to give accommodation and board to students at 35s a week Outbuildings have been converted into a pathological laboratory 45 feet long, this has been well equipped from the parent hospital, and the museum specimens have also been brought down The library is housed in the "silence room," which is also used for lectures, and the epidiascope has its place in the games room, which offers other attractions in the form of table-tennis, darts and a piano Students do their clinical work at Ashridge and at Stanmore Royal National Orthopædic Hospital, to which they are taken by a motor coach of character Enthusiasm for gardening is evident among Chaulden residents, especially for raising vegetables They have an active Home Guard section which is attached to the local contingent At Stanmore they get medical, surgical, orthopædic, gynæcological and special experience in abundance, but feel the lack of outpatients The Cambridge University Medical Society's analysis shows, however, that with access to 3000 beds students at Charing Cross are getting wider experience than students of any other metropolitan teaching hospital except the London

St George's Hospital

St George's takes about a hundred students, all men The sector to which it belongs is not perhaps as happily placed as some, because there is no large outlying hospital which could be taken over and staffed for teaching, with adequate grouping of patients and students One of the sector hospitals is under the control of the local authority and the others are hutted hospitals built by the Ministry of Health and attached to the local public assistance institutions Thus it has not been easy to control the training of students transferred to them Dispersal of students to these hospitals became necessary last September, and in spite of lack of suitable cases for teaching, and lack of teachers—since more than half the staff have joined the forces—medical education has been maintained at something like its peace-time level The hospital is planning, however, to open a country branch of 150 beds of its own within twenty miles of London, where it is proposed to equip a large private house and grounds as a medical school Students will thus be centralised in excellent surroundings The bulk of bedside teaching and laboratory work will be done at this branch, which is close enough to London for students to attend the flourishing outpatient department at the parent hospital Some students, mainly seniors, will have to remain in London to assist in treatment of casualties A R P duties undertaken by the students have contributed little to their medical education, but the efficient reception and treatment of casualties would hardly have been possible if the students had not undertaken the accessory duties of stretcher-bearing and fire-fighting Students are also attached to the blood transfusion, resuscitation and surgical teams, where the experience they gain is undoubtedly valuable, but of little help to them in passing examinations

Guy's Hospital

Students in the preclinical years are still working at Tunbridge Wells near the sector hospital of Pembury Four large buildings have been equipped and furnished, some as lecture-rooms and laboratories and others as hostels with accommodation for about 300 students The remaining students are living in lodgings in the district The largest of the four buildings, Sherwood Park, about a mile and a half from the town, contains the chemistry laboratories and dissecting-rooms, lecture-rooms, dining, reading and common rooms and the offices of the dean The physiology department is in another of the houses and the biochemistry and physics department in a third, since last year the physics department has been moved to roomier quarters in a neighbouring building Teachers and students have been brought into closer contact Athletic facilities are available for rugger, swimming, golf, tennis, squash and even rowing on the Medway Students in the clinical years are working either at Guy's itself, which has been able to carry on in spite of serious damage, or at the sector hospitals at Farnborough, Pembury and Orpington At Guy's, ward rounds, outpatients and courses of lectures are being conducted as in peace time The number of beds available for teaching has, of course, been reduced, but their loss has been more than balanced by the number of beds available in the sector hospitals, and recently a country branch of the hospital has been opened in the Wildernesse, a country club, at Seal, near Sevenoaks This is to be called Guy's U S A Hospital because the Hollywood branch of the "Bundles for Britain" organisation is taking a keen interest in it, and is providing much valuable equipment This new annexe contains about 110 beds, but is unfortunately too small to house any part of the medical school Teaching rounds are being held there, however, so that it is playing some part in medical education At Farnborough and Pembury the teaching is undertaken by members of Guy's staff who are living there After a preliminary period at Pembury, clinical students go to the sector hospitals to begin their appointments as clerks and dressers After that they return to Guy's for the remainder of their training, with the exception of the obstetric course which is taken either at Farnborough or Pembury where there are large maternity wards During the past year the examinations for entrance scholarships and most of the prize examinations have been conducted as usual At present all students qualifying can take appointments as resident officers at Guy's or in various hospitals in the sector

King's College Hospital

The medical school has now settled down, in so far as that is possible at present Some students do their preclinical work at King's College (now a guest at Birmingham), others come from Oxford or Cambridge In peace-time students are only admitted twice a year, but at present they are being admitted as soon as they pass their second M B examination Newcomers to clinical work go at once to Horton Emergency Hospital at Epsom, where they are either housed in the hospital or billeted in the town During the first three months they take an elementary course in clinical medicine and surgery and a full course in pathology in the laboratories of Epsom College They spend their second six months at the Blind School Emergency Hospital, at Leatherhead attached to medical and surgical firms, and during this period they are seconded for a fortnight to King's College Hospital and Croydon General for experience in casualty dressing At the end of the six months at Leatherhead students return to Horton and continue as ward clerks and dressers for another year They are attached to various firms for four months at a time The firms are mixed, each having a physician, a general surgeon and a special surgeon attached to it In addition to clinical work the students get their anæsthetic experience during this year Towards the end of it they are seconded in groups to Cuckfield, where they see practice in children's diseases, and to Hayward's Heath Emergency Hospital for study of nervous diseases They get their obstetric experience, both hospital and district, at the Mayday Hospital, Croydon, and return for their final period to King's College Hospital, where they live in, attend the outpatient department, and assist in the resuscitation room and the wards when air-raid casualties are admitted

London Hospital

Students can come to the hospital direct, or from one of the universities The London is responsible for Sectors I and II, it has escaped serious damage and remains the headquarters of the medical school The beds have been reduced from the pre-war figure of 900 to 350 An annexe has been opened at Brentwood with 360 beds The organisation of the E M S at the beginning of the war brought the medical school into relation with all the hospitals in Essex and many in London, Middlesex and Hertfordshire The clinical facilities of the school have thus been greatly extended by the war Chemistry, physics and biology are taught at Queen Mary College, now transferred to Cambridge The department of anatomy, physiology and pharma-to pass a first examination in physics, biology and chemistry, a second in anatomy and physiology, and finals in pathology, pharmacology and general therapeutics, forensic medicine, toxicology, public health, medicine, surgery and obstetrics All fellowships have been withdrawn and no award will be made while the war lasts Scholarships will still be awarded No changes have been made in the regulations governing medical degrees

Medical graduates are eligible for the degree of M D on presenting a thesis and attending an oral examination on the subject of the thesis , or by passing an examination in medicine together with a selected branch of medicine The degree of Ch M is awarded on the result of an examination only The university also confers the degree of Master of Orthopædic Surgery (M Ch Orth), after examination upon graduates in medicine of Liverpool and other approved universities The university offers diplomas in radiology tropical medicine, tropical hygiene and public health The courses for the degree of M Ch Orth and for diplomas in radiology and public health are suspended at present and it is uncertain whether the courses for the diplomas in tropical medicine and hygiene will be held Full particulars may be obtained from the Dean of the Faculty of Medicine, University of Liverpool *

Medical education in Liverpool during the past year has been somewhat influenced by raids An extra term was introduced during the summer vacation, which enabled students to complete their statutory classes so that they could, in their final year take posts in the hospitals They are being used as housemen in both voluntary and municipal hospitals provided there is a qualified man also in residence, and that some members of the clinical lecturing staff hold appointments there This has worked well on the whole, but the introduction of a vacation term between the second and third year (anatomy and physiology period) was not a success because the compressed teaching gave students too little time to assimilate their subjects Anatomy and physiology, loaded as they are with unfamiliar terminology and new material, must have time to soak into the mind The extra term at this period has therefore been given up, but it is being maintained for students in their clinical years Students in their preclinical years are required to join the U T C Fourth-year students attached to hospitals which were seriously damaged in raids were transferred to firms in undamaged hospitals They undertake fire-watching at hospitals and at the university, and are also attached to hospital teams as dressers, for service during and after raids

It has not been easy to maintain an adequate standard of clinical teaching for fifth- and sixth-year students The depleted staffs have naturally faced increased professional work, and their teaching time has been correspondingly curtailed , but everyone has done the best he can Transport between the university and hospitals evacuated to outlying sites has been difficult for students, but those with cars have used them to give lifts, and others have managed somehow, except when transport services were upset

VICTORIA UNIVERSITY OF MANCHESTER

New regulations have been adopted making it possible for extramural candidates who have fulfilled specified requirements to take the first M B examination Clinical work is carried out at the Royal Infirmary, the Royal Manchester Children's Hospital, the Ancoats Hospital, St Mary s Hospitals for Women and Children, the Skin and Eye Hospitals, the Tuberculosis Clinic and Hospital, and the Babies' Hospital Fees and scholarships have not been altered Students are required to pass four examinations and first or second class honours may be awarded on the results of the finals The first examination includes physics, organic and inorganic chemistry, and biology the second anatomy and physiology, the third pharmacology and pathology and bacteriology and the final which confers the degree of M B Ch B is in forensic medicine, hygiene and preventive medicine, medicine surgery, obstetrics and gynæcology

Medical graduates who wish to take the M D degree may either present a thesis or take an examination For the Ch M degree the graduate must take an examination or he may present a thesis, which, if it be judged of sufficient merit may exempt him from a part or the whole of the written examination Courses and examinations for the diplomas in public health, psychological medicine and bacteriology are at present suspended and no other medical diploma is offered by the university All regulations may be obtained from the Dean of the Medical School University of Manchester *

The war has made little difference to the curriculum training of the preclinical students being conducted in the medical school and university much as it was before the war The university buildings have suffered little in raids Some of the hospitals were damaged and students were for a time unable to get experience in some of the special departments but temporary arrangements were made and turned out well General honours courses in anatomy and physiology, biology and physiology or chemistry and physiology have been arranged for the B Sc degree but it is not expected that there will be many applicants for these courses till the end of the war A Staff and Students Committee (five representatives of each with power to coopt) was appointed last year to discuss changes in the curriculum suggested by the students For some years there has been a liaison between staff and students for this purpose and a standing Curriculum Committee for teachers in the faculty represented by heads of departments was established some years ago Tutorial classes are held whenever possible and are more popular with students than lectures , they would be more numerous but for problems of staff Several teachers are serving with the forces, and their place has been taken by those who had retired or were about to retire Senior students are helping as locums in various hospitals where the staff has been depleted, and are finding the experience and responsibility valuable Defence air-training and S T C duties seem to have had an exhilarating effect on all the medical students who have undertaken them To make the twenty-four hours go as far as possible they have curtailed many of their social activities Indoor and outdoor sports are pursued in the Physical Education Centre and on the playing fields but socials and dances have been cut down The Students' Representative Council has arranged for lectures by well-known people during the year which have proved popular The school has good air-raid shelters in the basement , if a warning is given in the day-time the building can be cleared and the students safely housed in about two minutes At night the university shelters are open to the public who are admitted by ticket Two medical students are on duty each night in addition to caretakers and wardens

UNIVERSITY OF LEEDS

Candidates will be admitted to the medical course if they have obtained a higher school certificate with chemistry, and either physics or botany at principal standard Those who have not obtained this exemption must take a pre-registration year and an examination in inorganic chemistry and physics or must take the pre-registration examination from school Except in cases approved by the Vice-Chancellor students must have reached the age of 17 before coming to the university Two terms of the medical course proper are given up to organic and physical chemistry botany and zoology with an examination in March The third term is spent in introductory anatomy and biochemistry followed by five terms of anatomy and physiology An additional term—during which the student takes pharmacology and introductory pathology and bacteriology—has been interpolated between the examination in anatomy and physiology and the beginning of clinical studies Thus the medical course now lasts 5 years and 9 months but the rearrangement of work is likely to result in a higher percentage of passes and more students should complete the course within the minimum period up to last October when this revised course was introduced less than half the students had been completing their final examination in the minimum time The examinations for the degrees of M B and Ch B are as follows the first in organic and physical chemistry botany and zoology, the second in anatomy and physiology, materia medica and pharmacology and the final in three parts—pathology and bacteriology public health and forensic

West London Hospital

The youngest medical school in London gives preference to women students Until 1937 it was a centre of postgraduate teaching, but when the British Postgraduate Medical School was opened the West London decided to become an undergraduate teaching hospital Many of the staff were called up at the outbreak of war, but there has been time since then to rearrange teaching on a sound basis The hospital has suffered nothing from raids beyond the loss of windows and it has not been necessary to evacuate it or to transfer the school to the country The number of students has fallen to just over half the normal complement, and the number of occupied beds has also been reduced But there is a good turnover of cases since a group of patients are transferred every week to outlying sector hospitals, and the effective teaching material is thus maintained quantitatively and qualitatively at pre-war level One change has been forced on the school by the destruction of the maternity block at the West Middlesex County Hospital where students were wont to take their obstetric course the Middlesex County Council has provided excellent alternative experience at their Bushey Maternity Home The closing of the pathological department of the West London at the outbreak of war made the teaching of pathology difficult but examination results show that attempts to solve this problem have been successful Thanks to the cooperation of the coroner, students have been able to attend post-mortem examinations at the public mortuary and have found the experience to be of great value It is often assumed that such autopsies are chiefly of medicolegal interest, but in fact a high proportion of them provide excellent examples of common pathological conditions The authorities at the British Postgraduate Medical School have also cooperated in pathological teaching and in addition to two annual courses of pathology held at the West London advanced instruction is carried out at the Hammersmith Hospital Most of the students being women, they have suffered no serious loss of study time from defence duties, but many of them did voluntary work in the East End shelters during the worst air-raid periods

Westminster Hospital

Up to the end of 1940 Westminster carried on with little change in medical education Then the hospital was hit, and after this, as a precaution, no patients were admitted for a time As students were faced with an absolute dearth of clinical material plans were made for some of them to work at Staines Emergency Hospital and a hostel was taken there which would accommodate 20 of them at a time Teaching has been conducted by the Westminster staff and by the Middlesex County Council and E M S staff of the hospital It was soon possible to open some of the Westminster wards again and at present students are doing six months' clinical work at Staines and the rest at Westminster, where lectures, demonstrations and tutorials have continued without interruption They get excellent midwifery experience under their own teachers at Ripley attending expectant mothers transferred from the Westminster district There is no lack of applicants to the medical school, which as usual is full to capacity Students in the final year are excused from civil defence duties

UNIVERSITY OF DURHAM

The medical school of the university is at King's College, Newcastle-on-Tyne Before admission to the medical course students must pass or gain exemption from matriculation and the premedical examination in chemistry, physics and biology The course for the premedical examination can be taken at King's College or at other approved institutions The student seeking an M B B S must spend at least three years in residence in the university and must pass in addition to the premedical examination, a second examination in anatomy, physiology, materia medica, pharmacology and pharmacy, a third examination in pathology, bacteriology, public health and medical jurisprudence, and finals in medicine, surgery, midwifery and gynæcology, psychological medicine, ophthalmology, diseases of the skin, ear, nose, and throat, and of children Clinical training is given at the Royal Victoria Infirmary, the Princess Mary Maternity Hospital, the Fleming Memorial Hospital for Sick Children, Newcastle-on-Tyne General Hospital, and the City Hospitals for infectious and mental diseases Resident appointments are available in these hospitals for newly qualified men and women

The degree of M D may be obtained by medical graduates either by taking an examination or submitting a thesis The M S degree is given on the results of an examination only A medical graduate who wishes to take the degree of Doctor of Surgery (D Ch) must have spent at least three years in the study of surgery, one of them in the university, and not less than six months in surgical study abroad, and must present a thesis and pass an examination The university also offers the degrees of bachelor and doctor of hygiene, and diplomas in public health and psychiatry Particulars of regulations for all university examinations may be obtained from the Dean of Medicine, the Medical School, Newcastle-on-Tyne

The war has caused no direct interruption of work at King's College, and A R P, air training or S T C duties seem to have had no ill effects on students' studies Several senior students have taken resident appointments before qualifying and it seems that such appointments add considerably to their knowledge, the gain being reflected in examination results Students' social and athletic activities have continued undisturbed

UNIVERSITY OF BIRMINGHAM

Students at Birmingham are required to pass five professional examinations the first in biology, chemistry and physics, the second in anatomy and physiology, the third in pathology and bacteriology, the fourth (taken at the end of five years' work, of which two have been spent in hospital) in forensic medicine and toxicology, public health and materia medica, pharmacology and therapeutics, and the final, which confers the degree of M B, Ch B, in medicine, surgery, midwifery and diseases of women, mental diseases and ophthalmology Clinical instruction is given in Birmingham United Hospital, comprising the General and the Queen Elizabeth Hospitals Many resident appointments are available, and fees and scholarships are unchanged

An M D degree is granted to graduates who present a thesis and pass an examination Candidates for the degree of Master of Surgery (Ch M) are also required to submit a thesis in addition to taking an examination, if the thesis is of exceptional merit the candidate may be released from the whole or part of the examination The university offers a diploma in public health, but the course for this examination is suspended during the war Particulars of the university regulations may be obtained from the Dean of the Medical Faculty the Medical School, Hospitals Centre, Birmingham, 15 *

The school is finding it possible to give full clinical instruction in the Birmingham United Hospital Several teachers in the anatomy and physiology departments are now on active service and this has meant that teaching in these subjects is now concentrated on the practical aspects A reader in pharmacology has been appointed, who will take up his duties during the coming session There is no evidence that civil defence duties are hindering students in their work, and physically their well-being has increased rather than diminished Athletics are practised, not perhaps quite at pre-war level, but with relatively little falling off in the standard

UNIVERSITY OF LIVERPOOL

Students are required to pass the university matriculation or an equivalent examination before admission They must spend three years in the university, but the remaining three years of the course can be spent at any recognised university or medical school Clinical training is given in the Royal Liverpool United Hospital and in five special and two municipal hospitals Plenty of resident appointments are available to those qualifying To obtain the M B, Ch B degree students are required pass a first examination in physics, biology and emistry, a second in anatomy and physiology, and nals in pathology, pharmacology and general thera-eutics, forensic medicine, toxicology, public health, edicine surgery and obstetrics All fellowships have een withdrawn and no award will be made while the ar lasts Scholarships will still be awarded No hanges have been made in the regulations governing edical degrees

---

* The entrance requirements for the Universities of Manchester Liverpool Leeds, Sheffield and Birmingham have been modified since the beginning of war they may be obtained from the Secretary Joint Matriculation Board 315 Oxford Road Manchester The faculty entrance requirements differ in each case from those of the university, they can be obtained from the Dean of the Faculty of Medicine in each university

Medical graduates are eligible for the degree of M D n presenting a thesis and attending an oral examination n the subject of the thesis , or by passing an examina-ion in medicine together with a selected branch of edicine The degree of Ch M is awarded on the result f an examination only The university also confers he degree of Master of Orthopædic Surgery (M Ch Orth), fter examination upon graduates in medicine of Liverpool and other approved universities The university ffers diplomas in radiology, tropical medicine, tropical ygiene and public health The courses for the degree f M Ch Orth and for diplomas in radiology and public ealth are suspended at present and it is uncertain hether the courses for the diplomas in tropical medicine nd hygiene will be held Full particulars may be btained from the Dean of the Faculty of Medicine, niversity of Liverpool *

Medical education in Liverpool during the past year has been somewhat influenced by raids An extra term was introduced during the summer vacation, which enabled students to complete their statutory classes so that they could, in their final year, take posts in the hospitals They are being used as housemen in both voluntary and municipal hospitals provided there is a qualified man also in residence, and that some members of the clinical lecturing staff hold appointments there This has worked well on the whole, but the introduction of a vacation term between the second and third year (anatomy and physiology period) was not a success because the compressed teaching gave students too little time to assimilate their subjects Anatomy and physiology, loaded as they are with unfamiliar terminology and new material, must have time to soak into the mind The extra term at this period has therefore been given up, but it is being maintained for students in their clinical years Students in their preclinical years are required to join the U T C Fourth-year students attached to hospitals which were seriously damaged in raids were transferred to firms in undamaged hospitals They undertake fire-watching at hospitals and at the university, and are also attached to hospital teams as dressers, for service during and after raids

During the past year Bristol has experienced the effects of raids and has had to put into practice plans for the evacuation of patients and dispersal of medical students to outlying hospitals. In some cases this has been inconvenient because of the distances which must be travelled: most of the medical inpatients, for example, have been transferred to Weston-super-Mare. Some of the clinical teachers have entered the Services but the rest are carrying on, and on the whole the work of the medical school is going on satisfactorily. One preclinical department was badly damaged by raids, but thanks to various ingenious makeshifts teaching was carried on almost without interruption. Students have not so far been seriously inconvenienced by A.R.P. duties, though they were kept busy enough during raids. They achieve experience of casualty work on such occasions by serving with first-aid parties attached to the surgical teams in hospital. Apart from this, A.R.P. duties are no doubt something of a hindrance to study. Up to this summer S.T.C. and fire-watching duties have not been compulsory, but from now on they are to be enforced; students doing clinical work, however, will be exempted from joining the S.T.C.

UNIVERSITY OF WALES

Students are admitted to the Welsh National School of Medicine after passing matriculation in the University of Wales or an equivalent examination. The applicants are numerous and the school is always crowded. The suggestion has been made that medical students might be required to pass a junior matriculation followed a year later by a senior matriculation which would include the premedical science subjects. This would mean that students admitted could begin at once with anatomy and physiology. In the ordinary way the Welsh student passing anatomy, physiology and organic chemistry three years after matriculation and at a high standard receives a B.Sc. and then begins his three years of clinical work. As a war measure the university is permitting those who have passed their second M.B. examination at the end of two years to begin their clinical work at once. An additional examination in second M.B. subjects—anatomy and physiology—is to be held in September. This means that the final examination for the degree of M.B., B.Ch. in medicine, surgery and midwifery, can be taken five years after the date of matriculation instead of six.

Graduates in medicine may take an M.D. degree by passing an examination and submitting a thesis to the judgment of the university. For the degree of M.Ch. they must also present a thesis and pass an examination. The university offers diplomas in public health and in tuberculous diseases. Full particulars may be obtained from the Provost, the Welsh National School of Medicine, Cardiff.

Preclinical students work at University College, Cardiff, and clinical students receive their training in Cardiff Royal Infirmary, Llandough Hospital, Whitchurch Mental Hospital and the City Lodge Hospital. The time-table has been subject to some upheavals during the last year, perhaps in sympathy with other things in Cardiff. Damage from raids made it necessary to empty the infirmary for a time, but the outpatient department was soon going again and 150 beds were opened for ordinary patients while others were reserved for casualties. The blackout added further complications, since outpatients—many of whom came from a distance—had to be seen in the mornings instead of the afternoons, which made the morning an extremely busy time. After the damage to the infirmary, medical and surgical units of about 50 beds each were transferred to Whitchurch Mental Hospital. Students have transport available for the three-mile journey, so that they can get their experience with the units in the usual way. Time-tables of lectures and practical work have been made to fit in, and the plan is working well. The new pathological institute of the school is now partly finished and in use, so that the bulk of lectures can be given there; it has suffered only slight damage from raids. The students have settled down well and take their share of fire-watching and defence duties. Some have joined the Home Guard; there is no O.T.C. in Cardiff. Seniors go out with mobile units, and also get regular instruction at the Welsh Blood Transfusion Centre. They have given valuable help in hospitals during air-raids, and in surgery their teachers lay special emphasis on war-injuries. Plans have been made to meet the complete loss, during a raid, of any of the hospitals attached to the school. It is unlikely that all of them would be put out of commission at once, so that reciprocal arrangements should be feasible. If the pharmacology or pathology departments, with their elaborate equipment, were destroyed the problem would be more difficult, but plans for mutual help have been made with University College, Cardiff.

A group of 34 University College Hospital students were received as guests last October; they have been doing medicine at Llandough Hospital and sharing the experience of the Welsh students in surgery and pathology; this has worked well, and both groups of students have been happy in the association. The U.C.H. students are not expecting to return to Cardiff next October, but the picture may be different again by then. The school has also experienced what the Provost aptly calls "evacuated examinations." Under the emergency regulations, the conjoint final examinations have been held at Cardiff, one examiner being a local teacher and one coming from London; this has worked out well. Qualified men and senior students are being appointed as residents in South Wales hospitals; in Cardiff there are enough qualified men to fill the posts available but this would leave the other hospitals short. Efforts are being made to distribute to each hospital a just proportion of qualified and unqualified residents. The Welsh National School is always happy in the number of applicants for admission to the medical course. This year is no exception; the joint academic committee of the school and University College have to adjudicate between 140 applicants for about 40 places.

UNIVERSITY OF ABERDEEN

Candidates for admission to the university must have passed the preliminary examination of the Scottish Universities Entrance Board, or some equivalent examination and must hold the board's certificate of fitness. Students seeking the M.B., Ch.B. degree are required to pass a first examination in physics, chemistry and biology; a second in anatomy and physiology; a third in materia medica, pathology, forensic medicine, and public health and infectious diseases; and finals in medicine, surgery, and midwifery and the diseases peculiar to women and infants. Fees, scholarships and resident appointments are unaffected by the war.

The degree of M.D. may be conferred on medical graduates who pass an examination and submit a thesis. The M.Ch. degree is conferred on similar terms, but if the thesis is of special merit the candidate may be exempted from the whole or part of the examination. The university offers a diploma in public health. Details of university regulations may be obtained from the Dean of the Faculty of Medicine, Aberdeen University.

Medical education has been little changed in Aberdeen. Students have been admitted in their usual numbers, and all the usual departments and hospitals are available to them, though the teaching staff is slightly reduced. A.R.P. and S.T.C. duties do not seem to have affected the standard of work. Students are required to live in the university residence on the hospital site for at least four months during their training—for two months while doing clinical midwifery and two months while doing clinical medicine and surgery. The university has lately had a new hall of residence for students built at Foresterhill, close to the general, maternity and children's hospitals, and the new university medical buildings; this is to be opened to residents in October. Aberdeen differs from the other Scottish universities in having started the new curriculum, based on the recommendations of the General Medical Council, in 1938; all had intended to adopt it, but the other Scottish universities had not begun it when war broke out. The effect of the new curriculum has been to extend the period of university training from 5 years (15 terms) to 5⅔ years (17 terms); the courses and examinations in natural sciences are included, under this arrangement, in the university course, instead of being taken from school as in the case in some other universities. Three years' experience at Aberdeen seems to show that the curriculum is giving satisfaction.

medicine, and medicine, surgery, obstetrics and therapeutics

For the M D degree candidates must present a thesis or pass an examination in a selected subject, or both The degree of Ch M is awarded on the result of an examination The university also offers diplomas in public health and in psychological medicine The course for the D P M has been suspended while the war lasts, but the D P H course was held last session, and will be held again in the coming session if sufficient candidates apply Particulars of the regulations may be obtained from the Dean of the Faculty of Medicine, University of Leeds *

Teaching has continued smoothly in spite of reduced staff and diminished clinical material In the preclinical years the routine work has been almost normal, even though accommodation has had to be found for about eighty students from the Middlesex Hospital with their teaching and technical staffs and equipment The departments of anatomy and physiology have thus been congested but the Middlesex staff and students have been welcome friends and have entered into the life of the Leeds school Courses in pathology and bacteriology have been unaffected and there has been no reduction in post-mortem work at the Leeds Infirmary *on which much pathological teaching depends* In the wards teaching has suffered from lack of clinical material and by the absence of members of the staff on war service , but in the last few months beds have been put into what will later become the new outpatient department Casualty and outpatient work continue as usual The university buildings have suffered no war damage and candidates for admission to the medical course are flooding in The school has rather limited general accommodation It was built to house a much smaller body of students than it now takes Fine new laboratories have been built for pathology, bacteriology and physiology but there has been no increase in space in library, common room or refectory Schemes for new buildings are under consideration but during the war, of course, nothing can be done about them A large part of the department of experimental pathology has been taken over by the Ministry of Health as a regional blood transfusion centre

The effect of the new reservation conditions entailing membership of the U T C , air training squadron or Home Guard cannot yet be forecast While membership of the U T C was voluntary it did not interfere materially with students' studies—but the volunteers have usually been of the type who will get on well in any case

UNIVERSITY OF SHEFFIELD

In Sheffield University medical school regulations, scholarships, fees and resident appointments are little changed Prospective students take a pre-registration examination or an examination of equivalent standing and are then required to pass four professional examinations the first in biology, chemistry and physics , the second in anatomy and physiology , the third in pathology and bacteriology, pharmacology, applied anatomy and applied physiology , and the final examination which confers the M B , Ch B in medicine, therapeutics, surgery and midwifery, forensic medicine and public health It has always been held, at Sheffield, that any abrupt break between the preclinical and the clinical parts of the curriculum is purely artificial—that no part of the student's studies can strictly be called preclinical The curriculum is therefore conducted as a unified study Anatomy and physiology are taught until the student's fifth year, long after he has passed his second professional examination, and he takes his examination in applied anatomy and applied physiology only a year before he qualifies His clinical work begins not with a dressership but with a six months' shepherding course under medical and surgical tutors, starting at a time when he has done only one year of anatomy and physiology , at the same time he is being introduced to bacteriology, pathology and pharmacology Clinical teaching is given at the Sheffield Royal Infirmary, the Sheffield Royal Hospital and the Jessop Hospital for Women

Graduates taking an M D degree must either pass an examination or submit a thesis, those taking an M Ch are required to pass an examination only The University grants no medical diplomas, but offers the degrees of bachelor and master of dental surgery, and the diploma of licentiate in dental surgery Details of the regulations may be obtained from the Dean of the Faculty of Medicine, University of Sheffield *

The war has interfered remarkably little with the normal routine of the medical school Bombing did minor damage, soon repaired, to the university buildings, without interrupting teaching Clinical instruction continues at all the teaching hospitals although the number of inpatients has been reduced For about a month while raids were going on outpatients were few, but numbers have now increased to the average war time level of about half to three-quarters of the peace-time numbers Sheffield has always taken a pride in the high number of beds available to every student, and can still offer a larger number than most schools in the country Plans have been made whereby, if the general hospitals should suffer serious damage, clinical teaching will be carried on at the municipal and auxiliary hospitals in the neighbourhood Maternity cases are now delivered in outlying hospitals, but there is plenty of living-accommodation near these, and students are having no difficulty in getting their proper experience

Each hospital has an A R P and an emergency medical scheme by which clinical students can be called into service in teams when they are needed Senior students are taking resident posts and have profited by the wider experience of clinical work and the increased responsibility Nearly all the students are doing some sort of war work The Ministry of Labour and National Service now requires that students in a reserved category should serve in either the S T C or U A S , and should submit a satisfactory report of progress every six months These requirements may mean that other war service has to be given up The authorities of the medical faculty have decided to apply for exemption from the Ministry's requirement for students entering their fourth year provided they offer their services in the emergency teams of an approved hospital Students have organised among themselves a compulsory service of fire-watchers for the university buildings Judging by examination standards their work has not suffered as a result of the distractions of war

The idea of having an extra term during the summer vacation has not found favour because it would dislocate the curriculum too much Clinical students continue their work throughout the summer in any case, and extra tuition at that time would not help to shorten the course for them In preclinical years an extra term, it is felt, would merely prevent students from doing work of national importance which many of them undertake during the summer—on the land and elsewhere Probably from now onwards most of them will be doing almost full-time training during the summer with the S T C The number of applicants for entry to the medical school has increased considerably, but since the number of men is limited by the official quota, the increase will be made up wholly of women

UNIVERSITY OF BRISTOL

Students who are admitted to the university must have passed a recognised school certificate examination with credit in five subjects, or an equivalent For the degree of M B , Ch B they are required to pass three examinations the first in physics, chemistry and biology , the second in anatomy, physiology, elementary pharmacology and elementary pathology , and the final, section I, in materia medica and pharmacy, pharmacology, pharmacotherapeutics and toxicology, pathology and bacteriology and section II in medicine, surgery and obstetrics

The degree of M D may be conferred on medical graduates who have passed the necessary examination or whose dissertations have been approved The degree of Ch M is offered to graduates who submit a thesis and take an examination in surgery A thesis of exceptional merit may win the candidate exemption from part of the examination The only diploma offered by the faculty of medicine at the university, at present, is in dental surgery The diploma in public health has been in abeyance for some years All regulations may be obtained from the Dean of the Faculty of Medicine, University of Bristol

---

* See footnote on p. 244

During the past year Bristol has experienced the effects of raids and has had to put into practice plans for the evacuation of patients and dispersal of medical students to outlying hospitals In some cases this has been inconvenient because of the distances which must be travelled most of the medical inpatients, for example, have been transferred to Weston-super-Mare Some of the clinical teachers have entered the Services but the rest are carrying on, and on the whole the work of the medical school is going on satisfactorily One preclinical department was badly damaged by raids, but thanks to various ingenious makeshifts teaching was carried on almost without interruption Students have not so far been seriously inconvenienced by A R P duties, though they were kept busy enough during raids They achieve experience of casualty work on such occasions by serving with first-aid parties attached to the surgical teams in hospital Apart from this, A R P duties are no doubt something of a hindrance to study Up to this summer S T C and fire-watching duties have not been compulsory, but from now on they are to be enforced , students doing clinical work, however, will be exempted from joining the S T C

UNIVERSITY OF WALES

Students are admitted to the Welsh National School of Medicine after passing matriculation in the University of Wales or an equivalent examination The applicants are numerous and the school is always crowded The suggestion has been made that medical students might be required to pass a junior matriculation followed a year later by a senior matriculation which would include the premedical science subjects This would mean that students admitted could begin at once with anatomy and physiology In the ordinary way the Welsh student passing anatomy, physiology and organic chemistry three years after matriculation and at a high standard receives a B Sc and then begins his three years of clinical work As a war measure the university is permitting those who have passed their second M B examination at the end of two years to begin their clinical work at once An additional examination in second M B subjects—anatomy and physiology—is to be held in September This means that the final examination for the degree of M B , B Ch in medicine, surgery and midwifery, can be taken five years after the date of matriculation instead of six

Graduates in medicine may take an M D degree by passing an examination and submitting a thesis to the judgment of the university For the degree of M Ch they must also present a thesis and pass an examination The university offers diplomas in public health and in tuberculous diseases Full particulars may be obtained from the Provost, the Welsh National School of Medicine, Cardiff

Preclinical students work at University College, Cardiff, and clinical students receive their training in Cardiff Royal Infirmary, Llandough Hospital, Whitchurch Mental Hospital and the City Lodge Hospital The time-table has been subject to some upheavals during the last year, perhaps in sympathy with other things in Cardiff Damage from raids made it necessary to empty the infirmary for a time, but the outpatient department was soon going again and 150 beds were opened for ordinary patients while others were reserved for casualties The blackout added further complications, since outpatients—many of whom came from a distance—had to be seen in the mornings instead of the afternoons which made the morning an extremely busy time After the damage to the infirmary, medical and surgical units of about 50 beds each were transferred to Whitchurch Mental Hospital Students have transport available for the three-mile journey, so that they can get their experience with the units in the usual way Time-tables of lectures and practical work have been made to fit in, and the plan is working well The new pathological institute of the school is now partly finished and in use, so that the bulk of lectures can be given there , it has suffered only slight damage from raids The students have settled down well and take their share of fire-watching and defence duties Some have joined the Home Guard , there is no O T C in Cardiff Seniors go out with mobile units, and also get regular instruction at the Welsh Blood Transfusion Centre They have given valuable help in hospitals during air-raids, and in surgery their teachers lay special emphasis on war-injuries. Plans have been made to meet the complete loss during a raid, of any of the hospitals attached to the school It is unlikely that all of them would be put out of commission at once, so that reciprocal arrangements should be feasible If the pharmacology or pathology departments, with their elaborate equipment, were destroyed the problem would be more difficult but plans for mutual help have been made with University College, Cardiff

A group of 34 University College Hospital students were received as guests last October, they have been doing medicine at Llandough Hospital and sharing the experience of the Welsh students in surgery and pathology , this has worked well, and both groups of students have been happy in the association The U C H students are not expecting to return to Cardiff next October, but the picture may be different again by then The school has also experienced what the Provost aptly calls " evacuated examinations " Under the emergency regulations, the conjoint final examinations have been held at Cardiff, one examiner being a local teacher and one coming from London , this has worked out well Qualified men and senior students are being appointed as residents in South Wales hospitals , in Cardiff there are enough qualified men to fill the posts available, but this would leave the other hospitals short Efforts are being made to distribute to each hospital a just proportion of qualified and unqualified residents The Welsh National School is always happy in the number of applicants for admission to the medical course This year is no exception , the joint academic committee of the school and University College have to adjudicate between 140 applicants for about 40 places

UNIVERSITY OF ABERDEEN

Candidates for admission to the university must have passed the preliminary examination of the Scottish Universities Entrance Board, or some equivalent examination and must hold the board's certificate of fitness Students seeking the M B , Ch B degree are required to pass a first examination in physics, chemistry and biology , a second in anatomy and physiology , a third in materia medica, pathology, forensic medicine, and public health and infectious diseases , and finals in medicine, surgery, and midwifery and the diseases peculiar to women and infants Fees, scholarships and resident appointments are unaffected by the war

* See footnote on p 244

During the past year Bristol has experienced the effects of raids and has had to put into practice plans for the evacuation of patients and dispersal of medical students to outlying hospitals. In some cases this has been inconvenient because of the distances which must be travelled: most of the medical inpatients, for example, have been transferred to Weston-super-Mare. Some of the clinical teachers have entered the Services but the rest are carrying on, and on the whole the work of the medical school is going on satisfactorily. One preclinical department was badly damaged by raids, but thanks to various ingenious makeshifts teaching was carried on almost without interruption. Students have not so far been seriously inconvenienced by A.R.P. duties, though they were kept busy enough during raids. They achieve experience of casualty work on such occasions by serving with first-aid parties attached to the surgical teams in hospital. Apart from this, A.R.P. duties are no doubt something of a hindrance to study. Up to this summer S.T.C. and fire-watching duties have not been compulsory, but from now on they are to be enforced; students doing clinical work, however, will be exempted from joining the S.T.C.

UNIVERSITY OF WALES

Students are admitted to the Welsh National School of Medicine after passing matriculation in the University of Wales or an equivalent examination. The applicants are numerous and the school is always crowded. The suggestion has been made that medical students might be required to pass a junior matriculation followed a year later by a senior matriculation which would include the premedical science subjects. This would mean that students admitted could begin at once with anatomy and physiology. In the ordinary way the Welsh student passing anatomy, physiology and organic chemistry three years after matriculation and at a high standard receives a B.Sc. and then begins his three years of clinical work. As a war measure the university is permitting those who have passed their second M.B. examination at the end of two years to begin their clinical work at once. An additional examination in second M.B. subjects—anatomy and physiology—is to be held in September. This means that the final examination for the degree of M.B., B.Ch. in medicine, surgery and midwifery, can be taken five years after the date of matriculation instead of six.

Graduates in medicine may take an M.D. degree by passing an examination and submitting a thesis to the judgment of the university. For the degree of M.Ch. they must also present a thesis and pass an examination. The university offers diplomas in public health and in tuberculous diseases. Full particulars may be obtained from the Provost, the Welsh National School of Medicine, Cardiff.

Preclinical students work at University College, Cardiff, and clinical students receive their training in Cardiff Royal Infirmary, Llandough Hospital, Whitchurch Mental Hospital and the City Lodge Hospital. The time-table has been subject to some upheavals during the last year, perhaps in sympathy with other things in Cardiff. Damage from raids made it necessary to empty the infirmary for a time, but the outpatient department was soon going again and 150 beds were opened for ordinary patients while others were reserved for casualties. The blackout added further complications, since outpatients—many of whom came from a distance—had to be seen in the mornings instead of the afternoons which made the morning an extremely busy time. After the damage to the infirmary, medical and surgical units of about 50 beds each were transferred to Whitchurch Mental Hospital. Students have transport available for the three-mile journey, so that they can get their experience with the units in the usual way. Time-tables of lectures and practical work have been made to fit in, and the plan is working well. The new pathological institute of the school is now partly finished and in use, so that the bulk of lectures can be given there; it has suffered only slight damage from raids. The students have settled down well and take their share of fire-watching and defence duties. Some have joined the Home Guard; there is no O.T.C. in Cardiff. Seniors go out with mobile units, and also get regular instruction at the Welsh Blood Transfusion Centre. They have given valuable help in hospitals during air-raids, and in surgery their teachers lay special emphasis on war-injuries. Plans have been made to meet the complete loss, during a raid, of any of the hospitals attached to the school. It is unlikely that all of them would be put out of commission at once, so that reciprocal arrangements should be feasible. If the pharmacology or pathology departments, with their elaborate equipment, were destroyed the problem would be more difficult, but plans for mutual help have been made with University College, Cardiff.

A group of 34 University College Hospital students were received as guests last October; they have been doing medicine at Llandough Hospital and sharing the experience of the Welsh students in surgery and pathology; this has worked well, and both groups of students have been happy in the association. The U.C.H. students are not expecting to return to Cardiff next October, but the picture may be different again by then. The school has also experienced what the Provost aptly calls "evacuated examinations." Under the emergency regulations, the conjoint final examinations have been held at Cardiff, one examiner being a local teacher and one coming from London; this has worked out well. Qualified men and senior students are being appointed as residents in South Wales hospitals; in Cardiff there are enough qualified men to fill the posts available, but this would leave the other hospitals short. Efforts are being made to distribute to each hospital a just proportion of qualified and unqualified residents. The Welsh National School is always happy in the number of applicants for admission to the medical course. This year is no exception; the joint academic committee of the school and University College have to adjudicate between 140 applicants for about 40 places.

UNIVERSITY OF ABERDEEN

Candidates for admission to the university must have passed the preliminary examination of the Scottish Universities Entrance Board, or some equivalent examination and must hold the board's certificate of fitness. Students seeking the M.B., Ch.B. degree are required to pass a first examination in physics, chemistry and biology; a second in anatomy and physiology; a third in materia medica, pathology, forensic medicine, and public health and infectious diseases; and finals in medicine, surgery, and midwifery and the diseases peculiar to women and infants. Fees, scholarships and resident appointments are unaffected by the war.

The degree of M.D. may be conferred on medical graduates who pass an examination and submit a thesis. The M.Ch. degree is conferred on similar terms, but if the thesis is of special merit the candidate may be exempted from the whole or part of the examination. The university offers a diploma in public health. Details of university regulations may be obtained from the Dean of the Faculty of Medicine, Aberdeen University.

Medical education has been little changed in Aberdeen. Students have been admitted in their usual numbers, and all the usual departments and hospitals are available to them, though the teaching staff is slightly reduced. A.R.P. and S.T.C. duties do not seem to have affected the standard of work. Students are required to live in the university residence on the hospital site for at least four months during their training—for two months while doing clinical midwifery and two months while doing clinical medicine and surgery. The university has lately had a new hall of residence for students built at Foresterhill, close to the general, maternity and children's hospitals, and the new university medical buildings; this is to be opened to residents in October. Aberdeen differs from the other Scottish universities in having started the new curriculum, based on the recommendations of the General Medical Council, in 1938; all had intended to adopt it, but the other Scottish universities had not begun it when war broke out. The effect of the new curriculum has been to extend the period of university training from 5 years (15 terms) to 5½ years (17 terms); the courses and examinations in natural sciences are included, under this arrangement, in the university course, instead of being taken from school as in the case in some other universities. Three years' experience at Aberdeen seems to show that the curriculum is giving satisfaction.

The ultimate test will be, as the dean points out, the final product which should be ready by 1944. If the war goes on the authorities propose to speed up the course at the end of the summer term of 1942 by introducing vacation courses, which will enable those who began the new curriculum in 1938 to qualify by September, 1943. This will be an interesting experiment, the new course being completed in 5 years instead of 5 years and 2 terms; it may even lead to a shortening of the long vacation when peace returns. But it is unlikely that the principle of speeding up will be approved except to meet an emergency like the present one.

UNIVERSITY OF EDINBURGH

Students are admitted when they have passed a preliminary or other examination recognised by the Scottish Universities Entrance Board and a pre-registration examination in physics and chemistry. Fees and scholarships are unchanged and the number of medical students has not been seriously affected by the war. The first examination is in chemistry, zoology, physics and botany; the second in anatomy and physiology, taken at the end of the second year; the third examination is in pathology, bacteriology, materia medica and therapeutics, and the final which confers the degree of M.B., Ch.B. in forensic medicine, public health, midwifery, surgery and medicine. During his fourth and fifth years the student spends six months at one of the city dispensaries, when he has an opportunity of visiting the sick poor in their own homes. Hospital work is carried out at the Royal Infirmary and at various municipal and special hospitals in the city.

Candidates for the M.D. degree must be medical graduates and must submit a thesis and pass an examination; they may be exempted from the examination by an exceptionally meritorious thesis. For the Ch.M. degree they must fulfil similar conditions. The university offers diplomas in public health, radiology, psychiatry, and tropical medicine and hygiene. Full particulars may be obtained from the Dean of the Faculty of Medicine, University of Edinburgh.

No parts of the curriculum have suffered specially as the result of war. The main courses have been carried on as usual but a few voluntary courses—such as that on the history of medicine—have been discontinued for the present. In 1939 the university authorities were working on the details of a new curriculum which was to increase the period of study from five years to six; but the war has prevented this from being put into operation. A number of short courses on subjects bearing on civil defence and medical work in the Forces have been introduced for senior students; those on medical aspects of A.R.P. and the treatment of gas injuries are now compulsory. In the clinical courses special instruction is given on first aid and the treatment of war wounds. Students have shown great keenness over these courses, and are anxious to prove useful in an emergency. Nearly all are attached to some organisation which will give service in air-raids. The senior students form part of fixed or mobile surgical teams, while junior students are attached to first-aid posts, hospital reception posts or stretcher-bearer parties. In the coming year all male first and second year students will be required to join the Senior Training Corps; those in the third, fourth and fifth years will probably be formed into special medical units and attached to the Home Guard. Civil defence duties do not seem to have hindered study; on the contrary, some duties of the kind have provided valuable experience.

Surgeons' Hall

The School of Medicine of the Royal Colleges of Edinburgh holds no professional examinations of its own but prepares students for the degrees of Edinburgh, London, and other universities, or more commonly for the qualifying examinations of the English, Irish or Scottish Conjoint Boards. Till the outbreak of war there were 700 students in attendance. The systematic classes are held in Surgeons' Hall and the New School, and clinical teaching is provided mainly in the Royal Infirmary, where students may gain resident appointments on qualifying. Particulars are to be had from the Dean, Surgeons' Hall, Edinburgh.

UNIVERSITY OF GLASGOW

Students are admitted who have passed the preliminary of the Scottish Universities Entrance Board or an equivalent examination, and who hold the board's certificate of fitness. There are four professional examinations for the M.B., Ch.B. degree, the first in botany, zoology, chemistry and physics, the second in anatomy and physiology, the third in materia medica and pathology, and the fourth in medical jurisprudence and public health, medicine, surgery and midwifery. Owing to the war a proposal to extend the course to six years has not yet been adopted. The Institute of Medicine caters not only for elementary instruction but for higher studies and research.

The degree of M.D. is conferred on graduates who submit a thesis and pass an examination; a specially good thesis will exempt a candidate from examination. Submission of a thesis and success in an examination are also required for the degree of Ch.M. The university offers a diploma in public health. Particulars of university regulations may be obtained from the Dean of the Faculty of Medicine, University of Glasgow.

On the whole it has been possible to continue medical teaching on normal lines. Many of the younger teachers are on active service, and the patients—particularly medical cases—are fewer, so that teaching facilities have been a little reduced; but it has not been necessary to discontinue any of the special courses. The main hospitals are undamaged and the routine of the students in the various years is not substantially altered. The demands made on students for civil defence service have not been burdensome. Service in the Senior Training Corps has hitherto been voluntary, but in the coming year will be compulsory for first, second and third year students. This may make some teaching difficulties, since the numbers are large, and some of the training will have to be given during the day. The senior students have been giving service in the E.M.S. hospitals during vacations and there are more applying for these posts than can be used. At present there are 1058 students in the medical school—850 men and 208 women.

Anderson College and St Mungo's College

These Glasgow medical schools have separate foundations. Anderson College, dating from the year 1800, receives about 700 students a year, both men and women. Courses are given in all preclinical subjects and clinical training is carried out in all the hospitals open to university students. No modifications of training have been made necessary by war conditions. The course prepares candidates for the examinations of all the licensing boards and for the university examinations of London, Edinburgh, Glasgow and Durham, provided the matriculation requirements of each are met. Hospital posts are now available for students who have completed their fourth year of study. Many distinguished men have been students of the college and it has given twenty professors to the University of Glasgow.

St Mungo's is the medical school of Glasgow Royal Infirmary, the largest general hospital in the city. The buildings are in the infirmary grounds and can accommodate 300 students, men and women. The courses in preclinical work are carried on in the college and clinical training is received in the wards of the infirmary and at the special hospitals of the city. The teaching staff has been little depleted by the claims of the Services and though clinical material has been diminished there has been no serious shortage of cases because the students, too, are fewer; many American students, for example, were prevented by the outbreak of war from returning after the summer vacation of 1939. The curriculum prepares students for examinations of the English, Scottish and Irish Conjoint Boards and, if certain conditions are fulfilled, for the examinations of the universities.

UNIVERSITY OF ST ANDREWS

Applicants always exceed vacancies at this medical school. About 55 are taken yearly, both men and women, and only those willing to take the full course are accepted. Students must hold the certificate of fitness of the Scottish Universities Entrance Board and are required to take four qualifying examinations for the degree of M.B., Ch.B., the first in botany, zoology, chemistry and physics; the second in anatomy and

physiology at the end of the second year, the third in materia medica, bacteriology, pathology, forensic medicine and public health, and the fourth and final in medicine, surgery and midwifery The student begins clinical work after completing the second examination and is trained in the Dundee Royal Infirmary and at various municipal hospitals and institutions Fees, scholarships and resident appointments have not been affected by the war No changes have been made in the regulations governing medical degrees and diplomas, but St Andrews, like other universities, has power under the Emergency Regulations to make any changes which become necessary

The M D and M Ch degrees may be conferred on graduates who present a thesis and take an examination The university offers a diploma in public health, now temporarily suspended, and a diploma in dental surgery Full details may be obtained from the Dean of the Medical Faculty, University of St Andrews, Dundee

Medical education has suffered scarcely at all from the impact of war There has been little damage to the university or infirmaries, and though many of the medical staff are on active service their duties have been taken over by others so that teaching has not suffered There have been no major changes in the courses held or in the number of hours spent in the different parts of clinical training The supply of cases has been well maintained, partly by using the facilities offered by institutions other than the main teaching hospitals Students have played their part in A R P , and hitherto membership of the O T C has been voluntary Next year, however, membership will be compulsory except for those in the later clinical years, and it will be necessary to modify teaching to fit in with these extra activities

. QUEEN'S UNIVERSITY OF BELFAST

This large medical school accommodates over 600 students After fulfilling the admission requirements of the university they must work for five years from the date of registration, and must pass the following examinations the first in chemistry, physics, zoology and botany; the second in anatomy, physiology and biochemistry, the third in pharmacology, pathology and bacteriology, the fourth in hygiene, medical jurisprudence and toxicology, and the final at the end of the fifth year in medicine, surgery, obstetrics and gynæcology This confers the degree of M B , B Ch , B A O Clinical teaching is given at the Royal Victoria and Mater Infirmorum hospitals and the maternity and special hospitals of the city

The M D and M Ch degrees may be conferred on graduates either on passing an examination or on submission of a thesis The degree of Master of Obstetric Science (M A O) is given to graduates who pass an examination, or submit a thesis Details of university regulations may be obtained from the Dean of the Faculty of Medicine, Queen's University of Belfast

Northern Ireland is not included in the conscription area, so that the medical faculty of the university has not so far been much affected The main difficulty has been the absence on war service of those who would otherwise be engaged in teaching Many of the students and the younger men on the staff have joined the forces, but older teachers have undertaken extra work, including some of those who had retired

UNIVERSITY OF DUBLIN

Students are admitted to Trinity College when they have passed an entrance examination in general subjects or an examination of equivalent standard They are required to take an arts course and the degree of B A before medical degrees can be conferred on them, but the course is so modified that they can take it concurrently with their medical studies Fees are unaffected by the war, there are numerous scholarships and prizes open to students and graduates and no change has been made in the regulations governing medical degrees and diplomas To obtain the degree of M B , B Ch , B A.O students must work for five years and pass a preliminary scientific and three professional examinations

An M D thesis may be conferred on a graduate who passes an examination and submits a thesis For the degree of M Ch graduates must pass a special examination, and the degree of Master in Obstetric Science (M A O) is also conferred on the results of examination The university grants diplomas in public health, psychological medicine, and gynæcology and obstetrics Details of the university regulations * may be obtained from the Dean, Trinity College, Dublin

Trinity College has been little affected by the war There have been no serious raids though casual bombs have been dropped on two occasions, doing considerable damage Citizens, however, do not live in expectation of raids, and there has been little evacuation. Education proceeds unperturbed Most of the hospitals have prepared themselves to deal with casualties if this becomes necessary, and many students have joined the Local Defence Force and taken courses in gas-instruction and fire-fighting These activities have not interfered with their attendance at lectures and practical classes

Schools of Surgery

The schools of surgery, including Carmichael and Ledwich schools, are attached by charter to the Royal College of Surgeons in Ireland They are carried on within the college buildings at St Stephen's Green, and are supervised and controlled by the council of the college There are spacious dissecting-rooms and biology, chemistry, physiology, pathology, bacteriology and pharmaceutical laboratories All lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the college Women students are admitted Particulars of the course may be obtained from the Registrar, Royal College of Surgeons in Ireland, Dublin

NATIONAL UNIVERSITY OF IRELAND

In the three University Colleges of Dublin, Cork and Galway the war has not materially influenced the medical schools In University College, Dublin, many students are giving help as volunteers in the medical services or in A R P units These duties do not seem to have interfered with attendance at lectures or examination results Fees, scholarships and regulations remain unchanged Students working for the degree of M B , B Ch , B A O must pass a premedical and four professional examinations

To obtain an M D degree, graduates must pass an examination , at University College, Cork, the candidate must also present a thesis but in Galway and Dublin the thesis is optional For the degree of M Ch a graduate must pass an examination and either submit a thesis or furnish evidence that he has been a member of the surgical staff of a hospital for at least two years The university offers diplomas in public health and psychological medicine Details of the university regulations * may be obtained from the Registrar, the National University of Ireland, 49, Merrion Square, Dublin

---

* The position of the practitioner qualifying in Eire is that (1) if he intends to practise only in Eire he need only register in the Register for Eire (2) if he intends to practise in Great Britain or Northern Ireland he will register in the Register kept by the General Medical Council and (3) if he is in doubt where he will practise he will register in both registers He will as he registers in one register, or in both registers, put himself under the disciplinary control of the one council or of both councils

---

Economy in Liver Extracts —The Ministry of Health have issued an order under the defence regulations, limiting, as a war time measure, the use of liver extracts The order provides that liver extracts shall only be administered to patients suffering from pernicious anæmia or other megalocytic anæmias and then only by injection These restrictions will not apply to preparations manufactured before Aug 31, 1941 Until now liver for medicinal preparations has been imported, as home supplies are used for food and shipping refrigeration space is urgently required for other needs Further, glycerin and alcohol, which are in immense demand for munitions, are used in the preparation of extracts of liver to be taken by mouth It is possible to achieve economy in the use of liver extracts without patients suffering any hardship Liver extract is a specific in the treatment of pernicious anæmia and other megalocytic anæmias only, and it has been proved that by far the most effective and economical way of administering it is by injection (*Lancet*, 1941, 1, 672) It does not, however, have the same specific effect on the other more common forms of anæmias, which can be effectively treated in other ways These patients, therefore, need not suffer, while ample supplies of liver will be assured for those who really need it

The ultimate test will be, as the dean points out, the final product, which should be ready by 1944 If the war goes on the authorities propose to speed up the course at the end of the summer term of 1942 by introducing vacation courses, which will enable those who began the new curriculum in 1938 to qualify by September, 1943 This will be an interesting experiment, the new course being completed in 5 years instead of 5 years and 2 terms , it may even lead to a shortening of the long vacation when peace returns But it is unlikely that the principle of speeding up will be approved except to meet an emergency like the present one

UNIVERSITY OF EDINBURGH

Students are admitted when they have passed a preliminary or other examination recognised by the Scottish Universities Entrance Board and a pre-registration examination in physics and chemistry Fees and scholarships are unchanged and the number of medical students has not been seriously affected by the war The first examination is in chemistry, zoology, physics and botany , the second in anatomy and physiology, taken at the end of the second year , the third examination is in pathology, bacteriology, materia medica and therapeutics and the final which confers the degree of M B , Ch B in forensic medicine, public health, midwifery, surgery and medicine During his fourth and fifth years the student spends six months at one of the city dispensaries, when he has an opportunity of visiting the sick poor in their own homes Hospital work is carried out at the Royal Infirmary and at various municipal and special hospitals in the city

Candidates for the M D degree must be medical graduates and must submit a thesis and pass an examination , they may be exempted from the examination by an exceptionally meritorious thesis For the Ch M degree they must fulfil similar conditions The university offers diplomas in public health, radiology, psychiatry, and tropical medicine and hygiene Full particulars may be obtained from the Dean of the Faculty of Medicine, University of Edinburgh

No parts of the curriculum have suffered specially as the result of war The main courses have been carried on as usual, but a few voluntary courses—such as that on the history of medicine—have been discontinued for the present In 1939 the university authorities were working on the details of a new curriculum which was to increase the period of study from five years to six , but the war has prevented this from being put into operation A number of short courses on subjects bearing on civil defence and medical work in the Forces have been introduced for senior students , those on medical aspects of A R P and the treatment of gas injuries are now compulsory In the clinical courses special instruction is given on first aid and the treatment of war wounds Students have shown great keenness over these courses, and are anxious to prove useful in an emergency Nearly all are attached to some organisation which will give service in air-raids The senior students form part of fixed or mobile surgical teams, while junior students are attached to first-aid posts, hospital reception posts or stretcher-bearer parties In the coming year all male first and second year students will be required to join the Senior Training Corps , those in the third, fourth and fifth years will probably be formed into special medical units and attached to the Home Guard Civil defence duties do not seem to have hindered study on the contrary, some duties of the kind have provided valuable experience

Surgeons' Hall

The School of Medicine of the Royal Colleges of Edinburgh holds no professional examinations of its own but prepares students for the degrees of Edinburgh, London, and other universities, or more commonly for the qualifying examinations of the English, Irish or Scottish Conjoint Boards Till the outbreak of war there were 700 students in attendance The systematic classes are held in Surgeons' Hall and the New School, and clinical teaching is provided mainly in the Royal Infirmary, where students may gain resident appointments on qualifying Particulars are to be had from the Dean, Surgeons' Hall, Edinburgh

QUEEN'S UNIVERSITY OF BELFAST

This large medical school accommodates over 600 students After fulfilling the admission requirements of the university they must work for five years from the date of registration, and must pass the following examinations the first in chemistry, physics, zoology and botany , the second in anatomy, physiology and biochemistry , the third in pharmacology, pathology and bacteriology, the fourth in hygiene, medical jurisprudence and toxicology, and the final at the end of the fifth year in medicine, surgery, obstetrics and gynæcology This confers the degree of M B , B Ch , B A O Clinical teaching is given at the Royal Victoria and Mater Infirmorum hospitals and the maternity and special hospitals of the city

The M D and M Ch degrees may be conferred on graduates either on passing an examination or on submission of a thesis The degree of Master of Obstetric Science (M A O) is given to graduates who pass an examination, or submit a thesis Details of university regulations may be obtained from the Dean of the Faculty of Medicine, Queen's University of Belfast

Northern Ireland is not included in the conscription area, so that the medical faculty of the university has not so far been much affected The main difficulty has been the absence on war service of those who would otherwise be engaged in teaching Many of the students and the younger men on the staff have joined the forces, but older teachers have undertaken extra work, including some of those who had retired

UNIVERSITY OF DUBLIN

Students are admitted to Trinity College when they have passed an entrance examination in general subjects or an examination of equivalent standard They are required to take an arts course and the degree of B A before medical degrees can be conferred on them, but the course is so modified that they can take it concurrently with their medical studies Fees are unaffected by the war, there are numerous scholarships and prizes open to students and graduates and no change has been made in the regulations governing medical degrees and diplomas To obtain the degree of M B , B Ch , B A.O students must work for five years and pass a preliminary scientific and three professional examinations

An M D thesis may be conferred on a graduate who passes an examination and submits a thesis For the degree of M Ch graduates must pass a special examination, and the degree of Master in Obstetric Science (M A O) is also conferred on the results of examination The university grants diplomas in public health, psychological medicine, and gynæcology and obstetrics Details of the university regulations* may be obtained from the Dean Trinity College, Dublin

Trinity College has been little affected by the war There have been no serious raids though casual bombs have been dropped on two occasions, doing considerable damage Citizens, however, do not live in expectation of raids, and there has been little evacuation. Education proceeds unperturbed Most of the hospitals have prepared themselves to deal with casualties if this becomes necessary, and many students have joined the Local Defence Force and taken courses in gas-instruction and fire-fighting These activities have not interfered with their attendance at lectures and practical classes

Schools of Surgery

The schools of surgery, including Carmichael and Ledwich schools, are attached by charter to the Royal College of Surgeons in Ireland They are carried on within the college buildings at St Stephen's Green, and are supervised and controlled by the council of the college There are spacious dissecting-rooms and biology, chemistry, physiology, pathology, bacteriology and pharmaceutical laboratories All lectures and *courses of practical instruction may be attended by* medical students who are otherwise unconnected with the college Women students are admitted Particulars of the course may be obtained from the Registrar, Royal College of Surgeons in Ireland, Dublin

NATIONAL UNIVERSITY OF IRELAND

In the three University Colleges of Dublin, Cork and Galway the war has not materially influenced the medical schools In University College, Dublin, many students are giving help as volunteers in the medical services or in A.R P units These duties do not seem to have interfered with attendance at lectures or examination results Fees, scholarships and regulations remain unchanged Students working for the degree of M B , B Ch , B A O must pass a premedical and four professional examinations

To obtain an M D degree, graduates must pass an examination , at University College, Cork, the candidate must also present a thesis but in Galway and Dublin the thesis is optional For the degree of M Ch a graduate must pass an examination and either submit a thesis or furnish evidence that he has been a member of the surgical staff of a hospital for at least two years The university offers diplomas in public health and psychological medicine Details of the university regulations* may be obtained from the Registrar, the National University of Ireland, 49, Merrion Square, Dublin

---

* The position of the practitioner qualifying in Eire is that (1) if he intends to practise only in Eire he need only register in the Register for Eire (2) if he intends to practise in Great Britain or Northern Ireland he will register in the Register kept by the General Medical Council , and (3) if he is in doubt where he will practise he will register in both registers He will as he registers in one register or in both registers, put himself under the disciplinary control of the one council or of both councils

---

ECONOMY IN LIVER EXTRACTS —The Ministry of Health have issued an order under the defence regulations, limiting, as a war-time measure, the use of liver extracts The order provides that liver extracts shall only be administered to patients suffering from pernicious anæmia or other megalocytic anæmias and then only by injection These restrictions will not apply to preparations manufactured before Aug 31, 1941 Until now liver for medicinal preparations has been imported, as home supplies are used for food and shipping refrigeration space is urgently required for other needs Further, glycerin and alcohol, which are in immense demand for munitions, are used in the preparation of extracts of liver to be taken by mouth It is possible to achieve economy in the use of liver extracts without patients suffering any hardship Liver extract is a specific in the treatment of pernicious anæmia and other megalocytic anæmias only, and it has been proved that by far the most effective and economical way of administering it is by injection (*Lancet*, 1941, 1, 672) It does not, however, have the same specific effect on the other more common forms of anæmias, which can be effectively treated in other ways These patients, therefore, need not suffer, while ample supplies of liver will be assured for those who really need it

The ultimate test will be, as the dean points out, the final product, which should be ready by 1944. If the war goes on the authorities propose to speed up the course at the end of the summer term of 1942 by introducing vacation courses, which will enable those who began the new curriculum in 1938 to qualify by September, 1943. This will be an interesting experiment, the new course being completed in 5 years instead of 5 years and 2 terms; it may even lead to a shortening of the long vacation when peace returns. But it is unlikely that the principle of speeding up will be approved except to meet an emergency like the present one.

UNIVERSITY OF EDINBURGH

Students are admitted when they have passed a preliminary or other examination recognised by the Scottish Universities Entrance Board and a pre-registration examination in physics and chemistry. Fees and scholarships are unchanged and the number of medical students has not been seriously affected by the war. The first examination is in chemistry, zoology, physics and botany, the second in anatomy and physiology, taken at the end of the second year, the third examination is in pathology, bacteriology, materia medica and therapeutics and the final which confers the degree of M.B., Ch.B. in forensic medicine, public health, midwifery, surgery and medicine. During his fourth and fifth years the student spends six months at one of the city dispensaries, when he has an opportunity of visiting the sick poor in their own homes. Hospital work is carried out at the Royal Infirmary and at various municipal and special hospitals in the city.

Candidates for the M.D. degree must be medical graduates and must submit a thesis and pass an examination; they may be exempted from the examination by an exceptionally meritorious thesis. For the Ch.M. degree they must fulfil similar conditions. The university offers diplomas in public health, radiology, psychiatry, and tropical medicine and hygiene. Full particulars may be obtained from the Dean of the Faculty of Medicine, University of Edinburgh.

No parts of the curriculum have suffered specially as the result of war. The main courses have been carried on as usual but a few voluntary courses—such as that on the history of medicine—have been discontinued for the present. In 1939 the university authorities were working on the details of a new curriculum which was to increase the period of study from five years to six, but the war has prevented this from being put into operation. A number of short courses on subjects bearing on civil defence and medical work in the Forces have been introduced for senior students; those on medical aspects of A.R.P. and the treatment of gas injuries are now compulsory. In the clinical courses special instruction is given on first aid and the treatment of war wounds. Students have shown great keenness over these courses, and are anxious to prove useful in an emergency. Nearly all are attached to some organisation which will give service in air-raids. The senior students form part of fixed or mobile surgical teams, while junior students are attached to first-aid posts, hospital reception posts or stretcher-bearer parties. In the coming year all male first and second year students will be required to join the Senior Training Corps; those in the third, fourth and fifth years will probably be formed into special medical units and attached to the Home Guard. Civil defence duties do not seem to have hindered study; on the contrary, some duties of the kind have provided valuable experience.

Surgeons' Hall

The School of Medicine of the Royal Colleges of Edinburgh holds no professional examinations of its own but prepares students for the degrees of Edinburgh, London, and other universities, or more commonly for the qualifying examinations of the English, Irish or Scottish Conjoint Boards. Till the outbreak of war there were 700 students in attendance. The systematic classes are held in Surgeons' Hall and the New School, and clinical teaching is provided mainly in the Royal Infirmary, where students may gain resident appointments on qualifying. Particulars are to be had from the Dean, Surgeons' Hall, Edinburgh.

UNIVERSITY OF GLASGOW

Students are admitted who have passed the preliminary of the Scottish Universities Entrance Board or an equivalent examination, and who hold the board's certificate of fitness. There are four professional examinations for the M.B., Ch.B. degree, the first in botany, zoology, chemistry and physics, the second in anatomy and physiology, the third in materia medica and pathology and the fourth in medical jurisprudence and public health, medicine, surgery and midwifery. Owing to the war a proposal to extend the course to six years has not yet been adopted. The Institute of Medicine caters not only for elementary instruction but for higher studies and research.

The degree of M.D. is conferred on graduates who submit a thesis and pass an examination; a specially good thesis will exempt a candidate from examination. Submission of a thesis and success in an examination are also required for the degree of Ch.M. The university offers a diploma in public health. Particulars of university regulations may be obtained from the Dean of the Faculty of Medicine, University of Glasgow.

On the whole it has been possible to continue medical teaching on normal lines. Many of the younger teachers are on active service, and the patients—particularly medical cases—are fewer, so that teaching facilities have been a little reduced, but it has not been necessary to discontinue any of the special courses. The main hospitals are undamaged and the routine of the students in the various years is not substantially altered. The demands made on students for civil defence service have not been burdensome. Service in the Senior Training Corps has hitherto been voluntary, but in the coming year will be compulsory for first, second and third year students. This may make some teaching difficulties, since the numbers are large, and some of the training will have to be given during the day. The senior students have been giving service in the E.M.S. hospitals during vacations and there are more applying for these posts than can be used. At present there are 1058 students in the medical school—850 men and 208 women.

Anderson College and St Mungo's College

These Glasgow medical schools have separate foundations. Anderson College, dating from the year 1800, receives about 700 students a year, both men and women. Courses are given in all preclinical subjects and clinical training is carried out in all the hospitals open to university students. No modifications of training have been made necessary by war conditions. The course prepares candidates for the examinations of all the licensing boards and for the university examinations of London, Edinburgh, Glasgow and Durham, provided the matriculation requirements of each are met. Hospital posts are now available for students who have completed their fourth year of study. Many distinguished men have been students of the college and it has given twenty professors to the University of Glasgow.

St Mungo's is the medical school of Glasgow Royal Infirmary, the largest general hospital in the city. The buildings are in the infirmary grounds and can accommodate 300 students, men and women. The courses in preclinical work are carried on in the college and clinical training is received in the wards of the infirmary and at the special hospitals of the city. The teaching staff has been little depleted by the claims of the Services and though clinical material has been diminished there has been no serious shortage of cases because the students, too, are fewer; many American students, for example, were prevented by the outbreak of war from returning after the summer vacation of 1939. The curriculum prepares students for examinations of the English, Scottish and Irish Conjoint Boards and, if certain conditions are fulfilled, for the examinations of the universities.

UNIVERSITY OF ST ANDREWS

Applicants always exceed vacancies at this medical school. About 55 are taken yearly, both men and women, and only those willing to take the full course are accepted. Students must hold the certificate of fitness of the Scottish Universities Entrance Board and are required to take four qualifying examinations for the degree of M.B., Ch.B., the first in botany, zoology, chemistry and physics, the second in anatomy and

physiology at the end of the second year, the third in materia medica, bacteriology, pathology, forensic medicine and public health, and the fourth and final in medicine, surgery and midwifery The student begins clinical work after completing the second examination and is trained in the Dundee Royal Infirmary and at various municipal hospitals and institutions Fees, scholarships and resident appointments have not been affected by the war No changes have been made in the regulations governing medical degrees and diplomas, but St Andrews, like other universities, has power under the Emergency Regulations to make any changes which become necessary

The M D and M Ch degrees may be conferred on graduates who present a thesis and take an examination The university offers a diploma in public health, now temporarily suspended and a diploma in dental surgery Full details may be obtained from the Dean of the Medical Faculty, University of St Andrews, Dundee

Medical education has suffered scarcely at all from the impact of war There has been little damage to the university or infirmaries, and though many of the medical staff are on active service their duties have been taken over by others so that teaching has not suffered There have been no major changes in the courses held or in the number of hours spent in the different parts of clinical training The supply of cases has been well maintained, partly by using the facilities offered by institutions other than the main teaching hospitals Students have played their part in A R P, and hitherto membership of the O T C has been voluntary Next year however, membership will be compulsory except for those in the later clinical years, and it will be necessary to modify teaching to fit in with these extra activities

. QUEEN'S UNIVERSITY OF BELFAST

This large medical school accommodates over 600 students After fulfilling the admission requirements of the university they must work for five years from the date of registration, and must pass the following examinations the first in chemistry, physics, zoology and botany; the second in anatomy, physiology and biochemistry, the third in pharmacology, pathology and bacteriology, the fourth in hygiene, medical jurisprudence and toxicology, and the final at the end of the fifth year in medicine, surgery, obstetrics and gynæcology This confers the degree of M B, B Ch, B A O Clinical teaching is given at the Royal Victoria and Mater Infirmorum hospitals and the maternity and special hospitals of the city

The M D and M Ch degrees may be conferred on graduates either on passing an examination or on submission of a thesis The degree of Master of Obstetric Science (M A.O) is given to graduates who pass an examination, or submit a thesis Details of university regulations may be obtained from the Dean of the Faculty of Medicine, Queen's University of Belfast

Northern Ireland is not included in the conscription area, so that the medical faculty of the university has not so far been much affected The main difficulty has been the absence on war service of those who would otherwise be engaged in teaching Many of the students and the younger men on the staff have joined the forces, but older teachers have undertaken extra work, including some of those who had retired

UNIVERSITY OF DUBLIN

Students are admitted to Trinity College when they have passed an entrance examination in general subjects or an examination of equivalent standard They are required to take an arts course and the degree of B A before medical degrees can be conferred on them, but the course is so modified that they can take it concurrently with their medical studies Fees are unaffected by the war, there are numerous scholarships and prizes open to students and graduates and no change has been made in the regulations governing medical degrees and diplomas To obtain the degree of M B, B Ch, B A.O students must work for five years and pass a preliminary scientific and three professional examinations

An M D thesis may be conferred on a graduate who passes an examination and submits a thesis For the degree of M Ch graduates must pass a special examination, and the degree of Master in Obstetric Science (M A O) is also conferred on the results of examination The university grants diplomas in public health, psychological medicine, and gynæcology and obstetrics Details of the university regulations * may be obtained from the Dean Trinity College, Dublin

Trinity College has been little affected by the war There have been no serious raids though casual bombs have been dropped on two occasions, doing considerable damage Citizens, however, do not live in expectation of raids, and there has been little evacuation. Education proceeds unperturbed Most of the hospitals have prepared themselves to deal with casualties if this becomes necessary, and many students have joined the Local Defence Force and taken courses in gas-instruction and fire-fighting These activities have not interfered with their attendance at lectures and practical classes

Schools of Surgery

The schools of surgery, including Carmichael and Ledwich schools, are attached by charter to the Royal College of Surgeons in Ireland They are carried on within the college buildings at St Stephen's Green, and are supervised and controlled by the council of the college There are spacious dissecting-rooms and biology, chemistry, physiology, pathology, bacteriology and pharmaceutical laboratories All lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the college Women students are admitted Particulars of the course may be obtained from the Registrar, Royal College of Surgeons in Ireland, Dublin

NATIONAL UNIVERSITY OF IRELAND

In the three University Colleges of Dublin, Cork and Galway the war has not materially influenced the medical schools In University College, Dublin, many students are giving help as volunteers in the medical services or in A R P units These duties do not seem to have interfered with attendance at lectures or examination results Fees, scholarships and regulations remain unchanged Students working for the degree of M B, B Ch, B A O must pass a premedical and four professional examinations

To obtain an M D degree, graduates must pass an examination at University College, Cork, the candidate must also present a thesis but in Galway and Dublin the thesis is optional For the degree of M Ch a graduate must pass an examination and either submit a thesis or furnish evidence that he has been a member of the surgical staff of a hospital for at least two years The university offers diplomas in public health and psychological medicine Details of the university regulations * may be obtained from the Registrar, the National University of Ireland, 49, Merrion Square, Dublin

---

* The position of the practitioner qualifying in Eire is that (1) if he intends to practise only in Eire he need only register in the Register for Eire (2) if he intends to practise in Great Britain or Northern Ireland he will register in the Register kept by the General Medical Council and (3) if he is in doubt where he will practise he will register in both registers He will as he registers in one register or in both registers put himself under the disciplinary control of the one council or of both councils

UNIVERSITY OF ST ANDREWS

Applicants always exceed vacancies at this medical school About 55 are taken yearly, both men and women, and only those willing to take the full course are accepted Students must hold the certificate of fitness of the Scottish Universities Entrance Board and are required to take four qualifying examinations for the degree of M B , Ch B , the first in botany, zoology, chemistry and physics , the second in anatomy and

physiology at the end of the second year, the third in materia medica, bacteriology, pathology, forensic medicine and public health, and the fourth and final in medicine, surgery and midwifery. The student begins clinical work after completing the second examination and is trained in the Dundee Royal Infirmary and at various municipal hospitals and institutions. Fees, scholarships and resident appointments have not been affected by the war. No changes have been made in the regulations governing medical degrees and diplomas, but St. Andrews, like other universities, has power under the Emergency Regulations to make any changes which become necessary.

The M.D. and M.Ch. degrees may be conferred on graduates who present a thesis and take an examination. The university offers a diploma in public health, now temporarily suspended, and a diploma in dental surgery. Full details may be obtained from the Dean of the Medical Faculty, University of St. Andrews, Dundee.

Medical education has suffered scarcely at all from the impact of war. There has been little damage to the university or infirmaries, and though many of the medical staff are on active service their duties have been taken over by others so that teaching has not suffered. There have been no major changes in the courses held or in the number of hours spent in the different parts of clinical training. The supply of cases has been well maintained, partly by using the facilities offered by institutions other than the main teaching hospitals. Students have played their part in A.R.P., and hitherto membership of the O.T.C. has been voluntary. Next year, however, membership will be compulsory except for those in the later clinical years, and it will be necessary to modify teaching to fit in with these extra activities.

QUEEN'S UNIVERSITY OF BELFAST

This large medical school accommodates over 600 students. After fulfilling the admission requirements of the university they must work for five years from the date of registration, and must pass the following examinations: the first in chemistry, physics, zoology and botany; the second in anatomy, physiology and biochemistry; the third in pharmacology, pathology and bacteriology; the fourth in hygiene, medical jurisprudence and toxicology; and the final at the end of the fifth year in medicine, surgery, obstetrics and gynæcology. This confers the degree of M.B., B.Ch., B.A.O. Clinical teaching is given at the Royal Victoria and Mater Infirmorum hospitals and the maternity and special hospitals of the city.

The M.D. and M.Ch. degrees may be conferred on graduates either on passing an examination or on submission of a thesis. The degree of Master of Obstetric Science (M.A.O.) is given to graduates who pass an examination, or submit a thesis. Details of university regulations may be obtained from the Dean of the Faculty of Medicine, Queen's University of Belfast.

Northern Ireland is not included in the conscription area, so that the medical faculty of the university has not so far been much affected. The main difficulty has been the absence on war service of those who would otherwise be engaged in teaching. Many of the students and the younger men on the staff have joined the forces, but older teachers have undertaken extra work, including some of those who had retired.

UNIVERSITY OF DUBLIN

Students are admitted to Trinity College when they have passed an entrance examination in general subjects or an examination of equivalent standard. They are required to take an arts course and the degree of B.A. before medical degrees can be conferred on them, but the course is so modified that they can take it concurrently with their medical studies. Fees are unaffected by the war, there are numerous scholarships and prizes open to students and graduates and no change has been made in the regulations governing medical degrees and diplomas. To obtain the degree of M.B., B.Ch., B.A.O. students must work for five years and pass a preliminary scientific and three professional examinations.

An M.D. thesis may be conferred on a graduate who passes an examination and submits a thesis. For the degree of M.Ch. graduates must pass a special examination, and the degree of Master in Obstetric Science (M.A.O.) is also conferred on the results of examination. The university grants diplomas in public health, psychological medicine, and gynæcology and obstetrics. Details of the university regulations* may be obtained from the Dean, Trinity College, Dublin.

Trinity College has been little affected by the war. There have been no serious raids though casual bombs have been dropped on two occasions, doing considerable damage. Citizens, however, do not live in expectation of raids, and there has been little evacuation. Education proceeds unperturbed. Most of the hospitals have prepared themselves to deal with casualties if this becomes necessary, and many students have joined the Local Defence Force and taken courses in gas-instruction and fire-fighting. These activities have not interfered with their attendance at lectures and practical classes.

Schools of Surgery

The schools of surgery, including Carmichael and Ledwich schools, are attached by charter to the Royal College of Surgeons in Ireland. They are carried on within the college buildings at St. Stephen's Green, and are supervised and controlled by the council of the college. There are spacious dissecting-rooms and biology, chemistry, physiology, pathology, bacteriology and pharmaceutical laboratories. All lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the college. Women students are admitted. Particulars of the course may be obtained from the Registrar, Royal College of Surgeons in Ireland, Dublin.

NATIONAL UNIVERSITY OF IRELAND

In the three University Colleges of Dublin, Cork and Galway the war has not materially influenced the medical schools. In University College, Dublin, many students are giving help as volunteers in the medical services or in A.R.P. units. These duties do not seem to have interfered with attendance at lectures or examination results. Fees, scholarships and regulations remain unchanged. Students working for the degree of M.B., B.Ch., B.A.O. must pass a premedical and four professional examinations.

To obtain an M.D. degree, graduates must pass an examination; at University College, Cork, the candidate must also present a thesis but in Galway and Dublin the thesis is optional. For the degree of M.Ch. a graduate must pass an examination and either submit a thesis or furnish evidence that he has been a member of the surgical staff of a hospital for at least two years. The university offers diplomas in public health and psychological medicine. Details of the university regulations* may be obtained from the Registrar, the National University of Ireland, 49, Merrion Square, Dublin.

---

* The position of the practitioner qualifying in Eire is that: (1) if he intends to practise only in Eire he need only register in the Register for Eire; (2) if he intends to practise in Great Britain or Northern Ireland he will register in the Register kept by the General Medical Council; and (3) if he is in doubt where he will practise he will register in both registers. He will, as he registers in one register, or in both registers, put himself under the disciplinary control of the one council or of both councils.

ECONOMY IN LIVER EXTRACTS.—The Ministry of Health have issued an order under the defence regulations, limiting, as a war time measure, the use of liver extracts. The order provides that liver extracts shall only be administered to patients suffering from pernicious anæmia or other megalocytic anæmias and then only by injection. These restrictions will not apply to preparations manufactured before Aug. 31, 1941. Until now liver for medicinal preparations has been imported, as home supplies are used for food and shipping refrigeration space is urgently required for other needs. Further, glycerin and alcohol, which are in immense demand for munitions, are used in the preparation of extracts of liver to be taken by mouth. It is possible to achieve economy in the use of liver extracts without patients suffering any hardship. Liver extract is a specific in the treatment of pernicious anæmia and other megalocytic anæmias only, and it has been proved that by far the most effective and economical way of administering it is by injection (*Lancet*, 1941, 1, 672). It does not, however, have the same specific effect on the other more common forms of anæmias, which can be effectively treated in other ways. These patients, therefore, *need not suffer*, while ample supplies of liver will be assured for those who really need it.

Degrees and Diplomas

EXAMINING BOARDS

English, Scottish and Irish Conjoint Boards

The Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England examines candidates for the qualifying diplomas of M R C S , L R C P Candidates satisfying the board's regulations in regard to the preliminary examination in general education, are eligible for admission to the premedical examination in chemistry, physics and biology , and are required to complete subsequently, at a recognised medical school, the professional curriculum of 57 months, including 33 months of clinical work Some war-time concessions have been authorised in the regulations . for example, examinations are being conducted at provincial centres as well as London , and clinical study may be undertaken at any hospital provided the dean of the candidate's school is satisfied as to the instruction available and signs the certificate of study Other modifications will be found in the Emergency Regulations which have been published and are to remain in force until the beginning of the academic year following the termination of the war Copies of these regulations, and a calendar showing the dates of examinations, may be obtained, free of charge from the Secretary to the Examining Board in England, the Examination Hall, Queen Square, London, W C 1

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement by which, after one series of examinations, held in Edinburgh, or Glasgow, or both, the student may obtain the diplomas—designated by the letters L R C P E , L R C S E , L R F P S G —of all three bodies Candidates may work for the examination of the Scottish Conjoint Board at any of the recognised medical schools of Great Britain and Ireland In 1938 the Triple Qualification committee of management adopted the suggestions of the General Medical Council for an extended medical curriculum, and since then the course has consisted of a year of premedical work followed by a five-year medical course The committee have now decided to revert to the 1937 regulations as a temporary war measure The course under these regulations lasts five years and includes, in addition to the pre-registration examination, four professional examinations the first examination in natural sciences (biology, chemistry and physics) , the second in anatomy and embryology, physiology, biochemistry and biophysics , the third in pathology and bacteriology, and pharmacology , and the final in medicine, surgery, midwifery, medical jurisprudence and public health The regulations in recent years have required students to complete the preliminary examination in natural sciences before beginning the five years of professional work , thus reversion to the 1937 regulations has the effect of bringing the whole preliminary and medical course within the period of five years The regulations may be obtained from the Registrar, 18, Nicolson Street, Edinburgh

The Conjoint Board of the Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland accept candidates for the L R C P I and L M , L R C S I and L M from most of the recognised medical schools at home and abroad There have been no changes in the regulations since the outbreak of war Full details can be obtained from the Registrar, Royal College of Surgeons in Ireland, Dublin

Apothecaries' Licences

The Society of Apothecaries of London grants the L M S S A Lond to candidates who pass in the premedical and primary examinations (which are held quarterly) and the final examination Final examinations are held monthly except in September The minimum period of study is normally 5 years, but as a war-time measure candidates will be allowed to sit for the primary examination in anatomy and physiology after 46 weeks' study, provided that this covers a period of not less than 15 months , that is to say, the candidate can sit after four terms work instead of five, and this will save him a term on the whole course The three parts of the final examination may be taken together or in any order Further information may be obtained from the Registrar, Apothecaries' Hall, Blackfriars Lane, E C 4

The Apothecaries' Hall of Ireland grants the L A H Dubl to students who pass the three professional examinations No changes have been made in the regulations, which can be obtained from the Registrar, 95, Merrion Square, Dublin

UNIVERSITY DEGREES

Bachelor of Medicine and Surgery

All the universities in the United Kingdom offer baccalaureate degrees in medicine and surgery They are conferred on the results of examinations which have been mentioned in the accounts already given of the various universities

HIGHER QUALIFICATIONS

Those who have graduated in medicine and surgery are at liberty to seek higher qualifications if they wish

Doctor of Medicine and Master of Surgery

Graduates holding a bachelor's degrees can take the degrees of Doctor of Medicine or Master of Surgery All the universities in Great Britain and Ireland confer such degrees The requirements, which vary, are noted in the accounts of the different universities At the University of Durham the degree of Doctor of Surgery (D Ch) is offered in addition to degree of Master of Surgery (M S)

Master in the Science of Obstetrics and Master of Midwifery

The Irish universities grant the degree M A O , the requirements for which are mentioned in the accounts of the universities concerned The Society of Apothecaries of London offers the qualification of Mastery of Midwifery (M M S A) The degree is given on the results of an examination, the requirements for which can be obtained from the Registrar, Apothecaries' Hall, Blackfriars Lane, E C 4

MEMBERSHIP AND FELLOWSHIP

The Royal College of Physicians of London confers the Membership (M R C P) which is obtained by examination and the Fellowship (F R C P) which is an honorary distinction Medical graduates over the age of 23 are at liberty to enter for the Membership examination, details of which can be obtained from the Secretary, Royal College of Physicians, Pall Mall East, London, S W 1

Fellows are selected annually, from the ranks of members, by the council of the college

The Royal College of Surgeons of England grants a Fellowship to Members or to graduates of recognised universities who pass the primary and final F R C S examinations Candidates for the final examination who, owing to war work, have been unable to comply with the regulation that requires six months' residence as house surgeon in a recognised hospital may, if they can produce certificates showing comparable experience either in the Services or in the E M S , apply for special consideration There are no other war-time concessions in the regulations, copies of which may be obtained from the Director of Examinations, the Examination Hall, Queen Square, London, W C 1

Medical graduates who have been registered, or eligible for registration, for at least three years, may apply for examination for Membership of the Royal College of Obstetricians and Gynæcologists (M R C O G) Particulars of the regulations may be obtained from the Secretary, Royal College of Obstetricians and Gynæcologists, 58, Queen Anne Street, London, W 1

The Fellowship (F R C O G) is granted to Members who are judged to have advanced the science and art of obstetrics and gynæcology

Graduates may become Members of the Royal College of Physicians of Edinburgh (M R C P E) on passing an examination, particulars of which may be obtained from the Secretary, 9, Queen Street, Edinburgh 2

The Fellows are selected annually from among the Members by the council of the college, and receive the degree of F R C P E

Fellowship of the Royal College of Surgeons of Edinburgh (F R C S E) is granted to medical graduates who pass the required examination , particulars of the regulations may be obtained from the Clerk of the College, Surgeons Hall, 18, Nicolson Street, Edinburgh

The Royal Faculty of Physicians and Surgeons of Glasgow grants, after examination, a Fellowship which is registrable by the General Medical Council as an additional qualification (R F P S G) The candidate is examined in either medicine or surgery, as he chooses, and in an additional subject selected from a list of seventeen Those who pass the examination are eligible for election to Fellowship by ballot The faculty may also elect without examination three candidates yearly who have been qualified at least twenty years, have reached the age of forty-five, and whose professional status is of a high order , and two others of high professional standing who have not reached the age of forty-five

Membership of the Royal College of Physicians of Ireland (M R C P I) is granted on the result of an examination, the details of which may be obtained from the Registrar of the College, 6, Kildare Street, Dublin

Fellows are elected by ballot, and receive the degree of F R C P I

Graduates seeking the Fellowship of the Royal College of Surgeons in Ireland (F R C S I) must pass in two examinations, a primary in anatomy and physiology and a final in surgery Further particulars may be obtained from the Registrar, the Royal College of Surgeons in Ireland, Dublin

The Faculty of Radiologists offers a Fellowship (F F R) to medical graduates of five years standing who have spent at least one year in general clinical work at an approved hospital, have practised radiology for three years and have held a radiological diploma for at least two years Candidates are required to pass an examination and submit a thesis Candidates who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery or pathology Full particulars may be obtained from the Warden, the Faculty of Radiologists, 32, Welbeck Street, London, W 1

SPECIAL DEGREES AND DIPLOMAS

The regulations for the following diplomas can be obtained by applying to the examining bodies concerned [1]

Public Health

A diploma in public health (D P H) is granted by the English and Scottish Conjoint Boards and, usually, by all the universities of the United Kingdom except Oxford, Cambridge and Sheffield The diplomas in public health usually granted by the Universities of Manchester and Bristol and the Irish Conjoint Board are at present in abeyance, and the D P H courses at the Universities of Liverpool and Birmingham have been suspended The courses at Leeds and Durham will be held if sufficient candidates apply Durham, in addition to the diploma in public health, offers the degree of bachelor of hygiene to medical graduates of any approved university who attend courses for part I of the examination at Durham , the degree of doctor of hygiene is conferred on those holding the B Hy who submit an approved thesis and pass in an oral examination

Psychological Medicine

The Universities of Durham, Edinburgh, Dublin, Ireland (National University), Belfast (Queen's University), and the English and Irish Conjoint Boards grant diplomas in psychological medicine The University of London grants an academic diploma in psychology The courses and examinations for the diplomas usually granted by the Universities of Leeds and Manchester are at present suspended A D P M course is held annually at the Maudsley Hospital in the early months of the year , although the Central Pathological Laboratory has been transferred to West Park Hospital, Epsom, and the Maudsley has been emptied of patients and the staff divided between Sutton and Mill Hill emergency hospitals, it has been possible to arrange an adequate period of training for D P M candidates at these three centres, and it is hoped that the course will be held next year as usual Information can be obtained from the Honorary Director of the Medical School, Central Pathological Laboratory, West Park Hospital, Epsom, Surrey

Radiology

The Faculty of Radiologists grants a Fellowship (F F R) which has already been mentioned The diploma of Cambridge (D M R E) will probably be discontinued after Oct 31 1942 The Universities of London, Liverpool and Edinburgh also grant diplomas (D M R) and the English Conjoint grants the D M R R C P & S Courses for the diploma at Liverpool University are at present suspended

Tropical Medicine

A diploma in tropical medicine is almost indispensable for those seeking medical appointments in the tropics Courses of instruction are given at the University of Edinburgh, the Liverpool School of Tropical Medicine[2] and the London School of Hygiene and Tropical Medicine [3] At the beginning of the war it was decided by the London and Liverpool schools and by the Colonial Office that courses should be held alternately in London and Liverpool for the present The London school has arranged a course to begin in September, so the Liverpool course will probably begin in January, 1942, but this has not yet been finally settled London University grants a diploma in tropical medicine (D T M) and tropical hygiene (D T H) and the University of Edinburgh and the London Conjoint Board each grant a D T M and H

Gynæcology and Obstetrics

The Royal College of Obstetricians and Gynæcologists grants a diploma (D R C O G) to practitioners who have had special postgraduate experience in obstetrics The University of Dublin also offers a diploma (D G O) for which a course is held at Trinity College and the Rotunda Hospital The degree of M M S A granted by the Society of Apothecaries of London has already been mentioned

Ophthalmology

Three examining bodies issue diplomas in ophthalmology—the University of Oxford (granting the D O), the English Conjoint Board (granting the D O M S) and the Irish Conjoint Board (granting the D O M S R C P and S I)

Laryngology and Otology

The English Conjoint Board offers a diploma (D L O) for those who have made a special study of the ear, nose, pharynx and larynx

Anæsthetics

The English Conjoint Board also offers a diploma in anæsthetics (D A) Candidates must have special experience in giving anæsthetics

Child Health

Diplomas in child health (D C H) are now well established The English Conjoint Board grants one and the Irish Conjoint has lately followed suit

Tuberculous Diseases

The University of Wales grants a diploma in tuberculous diseases (T D D) and offers a course of instruction. A limited number of appointments for part-time assistant tuberculosis physicians are advertised annually in September by the Welsh National Memorial Association, enabling suitably qualified and selected candidates to study for the diploma

Bacteriology

Diplomas in bacteriology are ordinarily granted by the Universities of London and Manchester The course for the London University examination would normally be held at the London School of Hygiene and Tropical Medicine, but has been suspended during the war At Manchester both the course and the examination have been suspended

Clinical Pathology

The University of London offers a diploma in clinical pathology (D C P) A year's course of study is required

---

[1] Addresses of university officials are given in the section on Medical Schools , addresses of the Conjoint Boards on p 250

[2] Details may be obtained from the Laboratory Secretary, Liverpool School of Tropical Medicine, Pembroke Place

[3] Details may be obtained from the Dean, London School of Hygiene and Tropical Medicine, Keppel Street, W C 1

POSTGRADUATE STUDY IN LONDON

THE war has interfered with provisions for postgraduate study by reducing the number of beds available for teaching and by scattering the teaching staffs, but there are still facilities available for those who need them The undergraduate medical schools still provide opportunities of work for higher examinations for their own graduates, although the division of both hospitals and staffs has made this more difficult Most schools which normally take postgraduate students fall into one of three groups —

(A) Those hospitals which are carrying on much the same teaching facilities as before the war

(B) Those hospitals which, as a result of bomb damage or the need for reserving beds for the E M S , have little or no facilities for inpatient teaching, but which continue to teach in outpatient departments, and still offer resident appointments , in some of these selected students can be taken on as clinical assistants and in most of them hospital practice is available by arrangement with the dean

(C) Those hospitals which have had to suspend postgraduate teaching altogether, but which still appoint resident officers and in some cases clinical assistants

The refresher courses for insurance practitioners organised by the Ministry of Health before the war are still suspended, but equivalent instruction is still provided in London by a programme selected from the activities of the various departments of the British Postgraduate Medical School, and to a large extent by practice at the Prince of Wales's, Hampstead General, and Metropolitan Hospitals

GENERAL HOSPITALS

At the British Postgraduate Medical School (group A), although the number of beds is reduced and the full-time staff depleted by the Services, teaching is continuing on pre-war lines The ordinary programmes are being carried on in medicine, surgery, obstetrics and gynæcology, and pathology, and the principle is maintained of continuous teaching by the ordinary British methods of bedside tuition and lectures rather than by specific courses The teaching is of a high standard, suitable both for those who merely wish to improve their knowledge and for candidates for higher examinations Special courses on war medicine, fractures, war surgery of the chest, the nervous system, the extremities and abdomen, and on operative surgery, are held in rotation on alternate weeks These intensive courses last a week, to suit the needs of officers in the Services They are advertised in advance in the medical papers , fees are 1 guinea a week for ordinary students and for special courses, except for the fracture course for which the fee is 5 guineas Officers of the forces and of the E M S can be admitted free It is proposed, if circumstances permit, to start the special course for the London University diploma in clinical pathology in October A limited number of students can be given a fortnight's special tuition in anæsthetics, the fee being 3 guineas

The Prince of Wales's, Hampstead General and Metropolitan Hospitals fall into group B, and the Royal Northern, the National Temperance and Queen Mary's Hospital, Stratford, into group C

SPECIAL COURSES

Public health —At the Royal Institute of Public Health and Hygiene all work, including the course for the D P H , is being carried on normally The annual congress, however, is not being held Since the beginning of war emergency accommodation has been kept available in case of need, but so far it has not been necessary to use it The course in public health usually held at the London School of Hygiene has been suspended

Psychological medicine —As already noted (p 251) most of the activities of the Maudsley Hospital (A) have been moved to the emergency hospitals at Mill Hill and Sutton

At the Tavistock Clinic so many of the staff have joined the Services that large-scale teaching has had to be suspended There are hopes that the postgraduate course in psychopathology and psychotherapy will be held at the clinic's war-time premises at Westfield College, Kidderpore Avenue, Hampstead , this course consists of lectures and tutorials together with clinical work under supervision from senior members of the staff Short courses for general practitioners will shortly held if possible , these will be advertised in the medic journals Sunday discussion group meetings will probably be resumed in the autumn

Tropical medicine —The course for the D T M & of the English Conjoint Board will be held as usual t year at the London School of Hygiene and Tropic Medicine , it begins on Sept 22 and lasts five month A number of short courses, each lasting a fortnight, i tropical medicine and parasitology are being held fro time to time at the school, for the benefit of medi officers in our own Services and those of our Allies civilians may also attend Considerable damage to th school building has not interrupted work

Neurology —At the National Hospital, Queen Squar (B) hospital practice is available to selected clinica clerks (5 guineas for three months, 7 guineas for s months), and outpatient clinics are held each mornin at 11 A M , on Monday to Friday (1 guinea for one month, 2 guineas for three months) The West End Hospital (B) holds special classes—consisting of demonstrations of cases with commentaries—for a month four times a year, before each M R C P examination The Maida Vale Hospital (B) provides hospital practice, and may be continuing D P M teaching if it is needed

Heart and lungs —At the Brompton Hospital (B) limited hospital practice is available, and courses are held in preparation for the M R C P and conjoint examinations The Royal Chest Hospital (B) provides outpatient practice and special courses on heart diseases in conjunction with the Fellowship of Medicine The London Chest Hospital, Victoria Park (B) has been damaged, but is reorganising and providing increasing facilities for hospital practice

Children —The Hospital for Sick Children, Great Ormond Street (B) is providing instruction only for selected candidates for the diploma of child health The Queen's (C) and Princess Elizabeth of York (C) Hospitals have suspended postgraduate teaching

Maternity —Queen Charlotte's (A) is continuing to offer facilities at Ravenscourt Park The City of London Hospital (C) has been damaged, and teaching is suspended Hospital practice in the maternity department of the British Postgraduate Medical School is available

Cancer and radiology —At the Royal Cancer Hospital (A) teaching continues as before the war Special courses are held for the final F R C S , both in surgery and in operative surgery, and postgraduate courses are held qualifying for the diplomas in medical radiology of London University and of the Conjoint Board The Mount Vernon Hospital (B) offers hospital practice in its hospital at Northwood , 50 beds are reserved for cancer cases and this number is likely to be increased Additional cancer cases are received under the E M S scheme

Ophthalmology —The Royal London Ophthalmic Hospital (A) is carrying on as usual at Moorfields The Central London (B) continues as usual, except that no special courses are being held

Ear, nose and throat —At the Central London Hospital (B) hospital practice and coaching classes by the registrars are available, but no special courses are held The Metropolitan Hospital (A) is continuing its teaching and classes on outpatients in London and Watford, but all inpatients are transferred to the E M S base hospital Golden Square Hospital (B) provides hospital practice

Orthopædics —The Royal National Orthopædic Hospital (B) has suspended teaching, but the outpatient department is open to postgraduates

Genito urinary and rectal diseases —The London Lock Hospital (A) continues to provide instruction for postgraduates who wish to obtain the 130 hours' instruction required by the Ministry of Health for a special certificate, and teaching facilities generally continue unaltered Hospital practice is available in the outpatient department of All Saints (B), St Paul's (B), and St. Peter's (B) Hospitals and the latter holds a special course at Colindale Hospital in September Hospital practice is available at St Mark's (B), where the staff is prepared to give a week's intensive course in proctology

Skins —Hospital practice is available in the outpatient department at the London School of Dermatology (B), and there is a regular teaching session in outpatients at the British Postgraduate School on Thursdays at 2 P M

THE LANCET

LONDON SATURDAY AUGUST 30 1941

Inquest on a Curriculum

KNOWLEDGE of medicine is handed from seniors to beginners, according to the Hippocratic rule and perhaps in no other profession is learning so generously and directly shared But medicine stands alone in that the leaders and teachers live and practise in a different world from the great body of the profession It is an old cry that the aim of the medical curriculum should be to turn out good general practitioners how do we set about it ? From the moment of registration the student is taught by specialists, most of whom have no experience of general practice At the end of the course and of a few resident appointments, he is well—even brilliantly—equipped to start specialising He has a sound general background of all that is rare in medicine and surgery but he has learned to think of common diseases as humdrum He can discuss points of technique in all the specialties , but he has had no chance to treat the minor ailments, because these do not reach the hospital clinic In the one direction—obstetrics—where specialisation would not come amiss he is underexperienced He has usually delivered about twenty normal maternity cases (without analgesia) and has watched the R O O dealing with abnormals in general practice normal cases will usually fall to the midwife while he is summoned often late, to the abnormal case He has had no instruction whatever in certification or the management of a panel practice , he is usually shaky on prescribing , he may or may not be a competent anæsthetist · he thinks the business of making the patient comfortable is work for the nurse , preventive medicine seems to him to be the province of the public-health service , his ideas about the social and industrial responsibilities of medicine are vague and general , and he does not even realise that to sign a patient off as " fit for work " is an act of faith unless he is clear what strains that work applies He begins his life's work as a fumbler lacking half the tools of his trade and he learns skill at the expense of his patients Every general practitioner remembers his first week in the surgery, the confusion of mind produced by the rich variety of certificates, the growing sense of disappointment as " just another rheumatism came in, the guesswork which supplemented his ignorance when the patient asked for the details of some nursing procedure To the patient he was a young chap not quite up to it , to himself he was a young chap far beyond it and both were true—he could have dealt competently with an obscure or alarming condition, he was only at a loss with chronic and minor illness But these are to be his life's work if he is ill-informed about them at the outset he is at a disadvantage , and if he is conditioned to find them boring he is handicapped indeed

There is another way in which the medical student's training fails him he has worked where it was always possible to give the patient something like the best in the way of examination, investigation, treatment feeding and environment He now finds that he is continually driven to makeshifts and compromises which seem, at first, to stamp him as a hypocrite He discovers not only that he cannot do the best for his patients but that he has not even been taught to do the best he can Of course he learns He picks up a hint from a colleague here, a trick from the district nurse there , he supplements inadequate diets with costly vitamins because he must not prescribe food he gives tonics where he would like to give blankets cod-liver oil where he should order a sojourn in the country He begins to realise that he can only patch up where, given proper equipment, he could restore Here the fault lies not wholly in his training , it is right that he should know the best in treatment and learn to apply it The defect is in a medical service still unequipped in many directions to command the essentials of healthy living And it is not our duty, any more than it is the duty of the crowner's quest, to give praise or blame, to bring any of the agents to judgment, but rather to find out by patient inquiry how the prewar curriculum came to be the poor frustrated thing it was and to share in the glorious task denied to the coroner of infusing new life into the old framework

In Quest of a Curriculum

THERE are grave difficulties about training a man to be a doctor and it would be all too easy in the present emergency to emphasise the utilitarian side at the expense of his fundamental education Witness the reaction against experimental method, contemptuously called *Kaninchen-medizin* in Central Europe This danger is naturally more vivid to the minds of teachers than of students Teachers see clearly that if practice is not based on a sound appreciation of scientific method and thought it will deteriorate rapidly when the student leaves his medical school They seek to provide a better grounding the suggestion reaching us from many deans is that physiology should be an integral part of the whole curriculum and that, in the teaching of anatomy, structure should be continually related to function At Sheffield anatomy and physiology are taught throughout the five years of training and an examination in these subjects has been introduced after the second M B a year before the finals Some feel that the time adjustment between preclinical and clinical work and between the start of clinical work and finals is wrong From St Thomas s comes the view that time is wasted by the student in cramming the minutiæ of anatomy and that the premedical subjects might well be disposed of by the attainment of an acceptable standard in matriculation or school certificate The student could then go to a central school of anatomy—there might be two for the London area—for 9–12 months He would concentrate on the essentials of anatomy and enough relevant physiology, taught by the anatomists, to explain function At the end of the course he would take an examination in which attainment of honours standard could qualify for the primary fellowship He would then join his clinical medical school, which would be equipped with a department of physiology For a year he would study normal physiology, physiological chemistry and clinical methods, including the use of stethoscope, auroscope and ophthalmoscope, and would learn to interpret radiograms , he would also learn the technique of urine-testing, blood-examination and other laboratory tricks He would take another examination at the end of a year before passing on to clinical work and the study of morbid physiology

POSTGRADUATE STUDY IN LONDON

THE war has interfered with provisions for postgraduate study by reducing the number of beds available for teaching and by scattering the teaching staffs, but there are still facilities available for those who need them The undergraduate medical schools still provide opportunities of work for higher examinations for their own graduates, although the division of both hospitals and staffs has made this more difficult. Most schools which normally take postgraduate students fall into one of three groups —

(A) Those hospitals which are carrying on much the same teaching facilities as before the war

(B) Those hospitals which, as a result of bomb damage or the need for reserving beds for the E M S, have little or no facilities for inpatient teaching, but which continue to teach in outpatient departments, and still offer resident appointments, in some of these selected students can be taken on as clinical assistants and in most of them hospital practice is available by arrangement with the dean

(C) Those hospitals which have had to suspend postgraduate teaching altogether, but which still appoint resident officers and in some cases clinical assistants

The refresher courses for insurance practitioners organised by the Ministry of Health before the war are still suspended, but equivalent instruction is still provided in London by a programme selected from the activities of the various departments of the British Postgraduate Medical School, and to a large extent by practice at the Prince of Wales's, Hampstead General, and Metropolitan Hospitals

GENERAL HOSPITALS

At the British Postgraduate Medical School (group A), although the number of beds is reduced and the full-time staff depleted by the Services, teaching is continuing on pre-war lines The ordinary programmes are being carried on in medicine, surgery, obstetrics and gynæcology, and pathology, and the principle is maintained of continuous teaching by the ordinary British methods of bedside tuition and lectures rather than by specific courses The teaching is of a high standard, suitable both for those who merely wish to improve their knowledge and for candidates for higher examinations Special courses on war medicine, fractures, war surgery of the chest, the nervous system, the extremities and abdomen, and on operative surgery, are held in rotation on alternate weeks These intensive courses last a week, to suit the needs of officers in the Services They are advertised in advance in the medical papers, fees are 1 guinea a week for ordinary students and for special courses, except for the fracture course for which the fee is 5 guineas Officers of the forces and of the E M S can be admitted free It is proposed, if circumstances permit, to start the special course for the London University diploma in clinical pathology in October A limited number of students can be given a fortnight's special tuition in anæsthetics, the fee being 3 guineas

The Prince of Wales's, Hampstead General and Metropolitan Hospitals fall into group B, and the Royal Northern, the National Temperance and Queen Mary's Hospital, Stratford, into group C

SPECIAL COURSES

Public health —At the Royal Institute of Public Health and Hygiene all work, including the course for the D P H, is being carried on normally The annual congress, however, is not being held Since the beginning of war emergency accommodation has been kept available in case of need, but so far it has not been necessary to use it The course in public health usually held at the London School of Hygiene has been suspended

Psychological medicine —As already noted (p 251) most of the activities of the Maudsley Hospital (A) have been moved to the emergency hospitals at Mill Hill and Sutton

At the Tavistock Clinic so many of the staff have joined the Services that large-scale teaching has had to be suspended There are hopes that the postgraduate course in psychopathology and psychotherapy will be held at the clinic's war-time premises at Westfield College, Kidderpore Avenue, Hampstead, this course consists of lectures and tutorials together with clinical work under supervision from senior members of the staff Short courses for general practitioners will shortly held if possible, these will be advertised in the medi journals Sunday discussion group meetings will pro ably be resumed in the autumn

Tropical medicine —The course for the D T M & of the English Conjoint Board will be held as usual t year at the London School of Hygiene and Tropic Medicine, it begins on Sept 22 and lasts five mont A number of short courses, each lasting a fortnight, tropical medicine and parasitology are being held fro time to time at the school, for the benefit of medi officers in our own Services and those of our Allie civilians may also attend Considerable damage to t school building has not interrupted work

Neurology —At the National Hospital, Queen Squar (B) hospital practice is available to selected clini clerks (5 guineas for three months, 7 guineas for months), and outpatient clinics are held each mornin at 11 A M, on Monday to Friday (1 guinea for one month 2 guineas for three months) The West End Hospit (B) holds special classes—consisting of demonstration of cases with commentaries—for a month four times a year, before each M R C P examination The Maida Vale Hospital (B) provides hospital practice, and may be continuing D P M teaching if it is needed

Heart and lungs —At the Brompton Hospital (B) limited hospital practice is available, and courses are held in preparation for the M R C P and conjoint examinations The Royal Chest Hospital (B) provides outpatient practice and special courses on heart diseases in conjunction with the Fellowship of Medicine The London Chest Hospital, Victoria Park (B) has been damaged, but is reorganising and providing increasing facilities for hospital practice

Children —The Hospital for Sick Children, Great Ormond Street (B) is providing instruction only for selected candidates for the diploma of child health The Queen's (C) and Princess Elizabeth of York (C) Hospitals have suspended postgraduate teaching

Maternity —Queen Charlotte's (A) is continuing to offer facilities at Ravenscourt Park The City of London Hospital (C) has been damaged, and teaching is suspended Hospital practice in the maternity department of the British Postgraduate Medical School is available

Cancer and radiology —At the Royal Cancer Hospital (A) teaching continues as before the war Special courses are held for the final F R C S, both in surgery and in operative surgery, and postgraduate courses are held qualifying for the diplomas in medical radiology of London University and of the Conjoint Board The Mount Vernon Hospital (B) offers hospital practice in its hospital at Northwood, 50 beds are reserved for cancer cases and this number is likely to be increased Additional cancer cases are received under the E M S scheme

Ophthalmology —The Royal London Ophthalmic Hospital (A) is carrying on as usual at Moorfields The Central London (B) continues as usual, except that no special courses are being held

Ear, nose and throat —At the Central London Hospital (B) hospital practice and coaching classes by the registrars are available, but no special courses are held The Metropolitan Hospital (A) is continuing its teaching and classes on outpatients in London and Watford, but all inpatients are transferred to the E M S base hospital Golden Square Hospital (B) provides hospital practice

Orthopædics —The Royal National Orthopædic Hospital (B) has suspended teaching, but the outpatient department is open to postgraduates

Genito urinary and rectal diseases —The London Lock Hospital (A) continues to provide instruction for postgraduates who wish to obtain the 130 hours' instruction required by the Ministry of Health for a special certificate, and teaching facilities generally continue unaltered Hospital practice is available in the outpatient department of All Saints (B), St Paul's (B), and St. Peter's (B) Hospitals and the latter holds a special course at Colindale Hospital in September Hospital practice is available at St Mark's (B), where the staff is prepared to give a week's intensive course in proctology

Skins —Hospital practice is available in the outpatient department at the London School of Dermatology (B), and there is a regular teaching session in outpatients at the British Postgraduate School on Thursdays at 2 P M

The Defence Services

The Central Medical War Committee of the British Medical Association is responsible for the supply of all doctors for the defence services

Royal Naval Medical Service

The usual regulations governing entry of medical and dental officers to the Royal Naval Medical Service are suspended during the war and the only medical officers being admitted are those granted temporary commissions in the Royal Naval Volunteer Reserve After the war any vacancies will probably be filled by selection of officers from among those who have served in the R N V R during the war

Candidates for the Royal Naval Dental Service must be under 28 and registered under the Medical or Dental Acts and must also have a registrable qualification in dental surgery Particulars of conditions of service of naval dental officers can be obtained from the Medical Director-General of the Navy Queen s House 64, St James's Street London, S W 1

So far only one woman medical officer has been appointed for service in the W R N S She holds the relative rank of a Surgeon Lieutenant R N V R and serves as medical superintendent attached to the W R N S headquarters at the Admiralty

Royal Army Medical Corps

No applications for regular commissions will be invited during the war for the Royal Army Medical Corps It is expected that after the war regular commissions to make up the establishment of regular officers of the corps will be granted first to those who served as emergency commissioned officers during hostilities All war-time appointments are emergency commissions for the duration of the war , no short-service appointments are being made at present

Recently qualified doctors wishing to be appointed to an emergency commission in the R A M C should apply to the secretary of the Central War Committee at B M A House or if resident in Scotland to the secretary of the Scottish Medical War Committee 7, Drumsheugh Gardens Edinburgh 3 Applicants should have held an appointment either as house-surgeon or house-physician for 6 months

Some women medical officers have already been accepted for general medical duties with the A T S Vacancies exist for more Women must be under 40 and fit for general service There are no vacancies for specialists at present Applications must be made through the Central Medical War Committee

ARMY DENTAL CORPS

No applications for regular commissions will be invited during the war, and it is expected that after the war any regular officers required will be made up at first from among those who have served as emergency commissioned officers No short-service appointments are being made at present, and all war-time appointments are for the duration of the war Recently qualified dental surgeons who wish to be appointed to an emergency commission in the A D C should apply to the Central Dental War Committee, 13 Hill Street London W 1, or if resident in Scotland to the Scottish Central War Committee c o the Department of Health for Scotland, Edinburgh 1

Royal Air Force Medical Branch

Commissions in the medical branch of the R A F are now given only to those appointed to the Royal Air Force Volunteer Reserve for duration of the war Short service and permanent commissions are at present in abeyance

Newly qualified medical officers are considered for service in the medical branch of the Royal Air Force after having completed six months house appointment in a civil hospital No appointments to commissions are made direct by the Air Ministry , candidates must register with the Central Medical War Committee, which allocates doctors for interview and medical examination at the Medical Directorate, Air Ministry Entry of doctors to commissions in the Medical Branch of the Royal Air Force Volunteer Reserve is normally in the rank of Flying Officer (corresponding to Lieutenant in the R A M C) and promotion to Flight Lieutenant is automatic after one year's service providing recommendation for the rank is satisfactory There are from time to time a very limited number of vacancies for doctors holding specialist qualifications and in selected cases a higher rank on entry is given Medical officers on entry are given a short course of instruction at the Medical Training Establishment and on completion of the course become available for posting Such postings may be to operational units training units recruits centres, general hospitals and station hospitals In addition to ordinary general medical work there are the important branches of aviation medicine and general preventive medicine and hygiene Medical officers are encouraged to make a special study of these

Owing to the large number of women now recruited into the W A A F the medical branch is appointing a certain number of women doctors to commissions in the branch under terms of service similar to those applying to male doctors , these women doctors are mainly employed in the care of W A A F personnel but are also available to replace male medical officers as and when necessary Women doctors entered with the Royal Air Force Medical Branch are not W A A F officers but medical officers of the Royal Air Force , they wear uniform of the same pattern and design as officers of the W A A F and in addition the badge of the Medical Branch of the Royal Air Force

There is a separate dental branch of the R A F and dental officers are not appointed to the medical branch During the war dental officers are being appointed through the Central Dental War Committee which has been organised by the British Dental Association Entry into regular service has been suspended and all accepted candidates are at present commissioned in the R A F Volunteer Reserve for the duration of the war

Home Guard

The Home Guard Medical Service was officially constituted on April 2 1941 and consists of senior medical officers with the rank of Lieutenant-Colonel, battalion medical officers who are Majors and under them company and platoon officers with the ranks of Captain and Lieutenant The services of these officers are entirely voluntary and they are appointed by the commanding officers of battalions, subject to the approval of the local medical war committee which has to give its certificate that their employment will not prejudice the efficiency of the civilian services In practice the appointment is usually recommended by the senior medical officer or battalion medical officer concerned with the consent of the committee Duties are clearly defined " the Medical Officer is to be regarded as a Medical Adviser to the Battalion Commanders, whose main functions are to arrange the medical facilities within sub-units in accordance with their probable operational needs and to organise and assist in the training of the personnel He is not to be expected to undertake the duties such as are normally carried out by the Regimental Medical Officer of an Infantry Battalion " The care of Home Guard casualties is the responsibility of local civilian authorities from the moment that they are placed in the ambulances provided by those authorities These ambulances are instructed to collect Home Guard casualties only from points at which they have been assembled by the arrangement of the H G Medical Service Since it is obvious that ambulances may not be available while invasion and attack from the air is actually in progress and that the hospitals to which casualties would normally be sent may be incapable of dealing with them, the arrangement of suitable casualty collecting posts is one of the chief duties of the H G medical officer His duties with regard to training are not arduous and he can if he does not feel equal to giving lectures and instructions himself call upon local R A M C units to provide officers for these purposes The most remarkable thing about his duties is that they do not include any form of medical treatment He has to arrange that such treatment will be available, and he may in fact if invasion comes, have to carry out much of this treatment in his civilian

which is medicine He would not be eligible to sit for finals until he had completed 36 months of clinical work, but to keep him mettled up there might be sessional examinations at the medical school At present students are able to sit for part of the finals within 30 months of the second M B , and thus the average student is cramming for a part of the final within 24 months of beginning clinical work This suggested curriculum, admirable as it is, lays emphasis chiefly on groundwork and is not directed towards the special needs of general practice

Students and general practitioners have different suggestions to make On the whole students see more of general practice than do their teachers , many of them are the children of general practitioners and many hear the opinions of recently qualified friends Moreover that concern for social conditions which springs from imaginative appreciation of a neighbour's hardships—socialism in the basic sense—flourishes among the young If we are not willing to put the world right in our early twenties we are poor citizens The British Medical Students Association (p 259) ask that the student should receive better training in preventive medicine and gain more experience of chronic and minor ailments and the simpler gynæcological conditions , that he should have a wider knowledge of public health, of national health insurance, of compensation and rehabilitation They see the general practitioner, in short, as part of the social welfare organisation of the country and would have him competent to undertake that duty Nor are they oblivious of the groundwork on which such training must rest They ask for greater integration in the curriculum, and for orientation courses which would bring the various subjects into proper relationship at the outset One subject in which an orientation course would be particularly valuable is anatomy , a teacher suggests that the whole body might be dissected rapidly before the class, by an expert, before students are allowed to begin on a part All who remember the bewilderment of their first month in the dissecting-room will agree with him Some of the detail might be cut out and he suggests that anatomy should be taught on younger subjects, preferably beginning with the fœtus, so that students may see the organs at various stages of development, not only in the degeneration or atrophy of old age

Not unnaturally, the most practical suggestions for improvement of the curriculum come from general practitioners themselves They would like the student to have free access to the patients in the chronic wards of infirmaries, to see more minor infectious illnesses like tonsillitis, and more minor injuries like sprains They would like him to have personal experience of dispensing, not of writing “ rep mist ” and leaving the rest to the dispenser , to be confident of giving a safe anæsthetic , to know some practical psychology and more about mental disease and defect , and to realise that there is no mystery about children's diseases or infant feeding They think he should know more about the trifling ills of women—such as vaginal discharge, dysmenorrhœa and menopausal symptoms—and that he should have some instruction about sterility and contraception He should be more adept at recognising the early stages of disease, especially of cancer, and of rheumatic disorders likely to lead to crippling Above all they would have him a competent obstetrician Some would like six months postgraduate work in midwifery to be compulsory for the general practitioner Others consider that instead of spending a year on general surgery and a month on midwifery, the periods might well be reversed, or at least more wisely distributed Students spend hours in the theatre watching major surgical and gynæcological procedures which, as general practitioners, they will never perform They enjoy it, naturally , most of us like to assist, in the French sense, while a skilled craftsman does his job, whether it be painting a picture, building a ship, or opening an abdomen But watching major operations is a waste of time in a crowded curriculum, and a scrutiny of the student's timetable would doubtless reveal other extravagances , one doctor reminds us of the time spent loitering in the front hall, awaiting dilatory chiefs Time saved from these and other pursuits might be spent with a good firm of general practitioners Some doctors think the grounding would be adequate if the student attended at such a practice once or twice a week for a month or two , some think he should be resident with the firm for periods ranging from a fortnight to six months , others think this experience could be postgraduate , but none doubts that the person to train another in general practice is the general practitioner This return to the apprenticeship system, they feel, is overdue They do not suggest that it can in any way replace formal clinical teaching , only that it should supplement it, occupying time which can be spared from less essential studies All are emphatic about the value of resident appointments and some would like such postgraduate experience to be compulsory for a man about to enter general practice

The foregoing opinions—whether from teachers, students or practising doctors—are home and Empire produce they are what we can learn from each other But the experience of other countries is also instructive, especially when it forms a comment, spoken or unspoken, on our own practice The accounts of medical education in various parts of the world set out on p 260 will repay study We have something to learn, for example, from the Spanish system of selection, by which the best opportunities go to the best students , from the high standard of general education expected of students in France , from the student discussion groups of Norway , from the German tradition of experience in several universities , from the keenness, diligence and team spirit found in Russian clinics , and from the American principle that medicine deals not with the disease alone but with its effects on the patient, the patient's family and the community Russia, travellers tell us, finds us backward in our treatment of women , Spain thinks the golden age of English medicine is over, Germans are politely astonished when they find an English institution efficiently run, and Americans have to stop and think when they are asked to name the advantages of English medical education It is time to make changes Remembering the old maxim for examination candidates—“ do the easy ones first ”—let us begin by introducing experience of general practice into the curriculum, and a higher standard of obstetric training among those deciding to become family doctors

The Defence Services

The Central Medical War Committee of the British Medical Association is responsible for the supply of all doctors for the defence services

Royal Naval Medical Service

The usual regulations governing entry of medical and dental officers to the Royal Naval Medical Service are suspended during the war and the only medical officers being admitted are those granted temporary commissions in the Royal Naval Volunteer Reserve After the war any vacancies will probably be filled by selection of officers from among those who have served in the R N V R during the war

Candidates for the Royal Naval Dental Service must be under 28 and registered under the Medical or Dental Acts and must also have a registrable qualification in dental surgery Particulars of conditions of service of naval dental officers can be obtained from the Medical Director-General of the Navy Queen's House 64, St James s Street London S W 1

So far only one woman medical officer has been appointed for service in the W R N S She holds the relative rank of a Surgeon Lieutenant R N V R and serves as medical superintendent attached to the W R N S headquarters at the Admiralty

So far only one woman medical officer has been appointed for service in the W R N S She holds the relative rank of a Surgeon Lieutenant R N V R and serves as medical superintendent attached to the W R N S headquarters at the Admiralty

Royal Army Medical Corps

No applications for regular commissions will be invited during the war for the Royal Army Medical Corps It is expected that after the war regular commissions to make up the establishment of regular officers of the corps will be granted first to those who served as emergency commissioned officers during hostilities All war-time appointments are emergency commissions for the duration of the war, no short-service appointments are being made at present

Recently qualified doctors wishing to be appointed to an emergency commission in the R A M C should apply to the secretary of the Central War Committee at B M A House or if resident in Scotland to the secretary of the Scottish Medical War Committee 7 Drumsheugh Gardens Edinburgh 3 Applicants should have held an appointment either as house-surgeon or house-physician for 6 months

Some women medical officers have already been accepted for general medical duties with the A T S Vacancies exist for more Women must be under 40 and fit for general service There are no vacancies for specialists at present Applications must be made through the Central Medical War Committee

ARMY DENTAL CORPS

No applications for regular commissions will be invited during the war and it is expected that after the war any regular officers required will be made up at first from among those who have served as emergency commissioned officers No short-service appointments are being made at present and all war-time appointments are for the duration of the war Recently qualified dental surgeons who wish to be appointed to an emergency commission in the A D C should apply to the Central Dental War Committee, 13 Hill Street London W 1, or if resident in Scotland to the Scottish Central War Committee c o the Department of Health for Scotland Edinburgh 1

Royal Air Force Medical Branch

Commissions in the medical branch of the R A F are now given only to those appointed to the Royal Air Force Volunteer Reserve for duration of the war Short service and permanent commissions are at present in abeyance

Newly qualified medical officers are considered for service in the medical branch of the Royal Air Force after having completed six months house appointment in a civil hospital No appointments to commissions are made direct by the Air Ministry candidates must register with the Central Medical War Committee which allocates doctors for interview and medical examination at the Medical Directorate, Air Ministry Entry of doctors to commissions in the Medical Branch of the Royal Air Force Volunteer Reserve is normally in the rank of Flying Officer (corresponding to Lieutenant in the R A M C) and promotion to Flight Lieutenant is automatic after one year s service providing recommendation for the rank is satisfactory There are from time to time a very limited number of vacancies for doctors holding specialist qualifications and in selected cases a higher rank on entry is given Medical officers on entry are given a short course of instruction at the Medical Training Establishment and on completion of the course become available for posting Such postings may be to operational units training units recruits centres general hospitals and station hospitals In addition to ordinary general medical work there are the important branches of aviation medicine and general preventive medicine and hygiene Medical officers are encouraged to make a special study of these

Owing to the large number of women now recruited into the W A A F the medical branch is appointing a certain number of women doctors to commissions in the branch under terms of service similar to those applying to male doctors, these women doctors are mainly employed in the care of W A A F personnel but are also available to replace male medical officers as and when necessary Women doctors entered with the Royal Air Force Medical Branch are not W A A F officers but medical officers of the Royal Air Force they wear uniform of the same pattern and design as officers of the W A A F and in addition the badge of the Medical Branch of the Royal Air Force

There is a separate dental branch of the R A F and dental officers are not appointed to the medical branch During the war dental officers are being appointed through the Central Dental War Committee which has been organised by the British Dental Association Entry into regular service has been suspended and all accepted candidates are at present commissioned in the R A F Volunteer Reserve for the duration of the war

Home Guard

The Home Guard Medical Service was officially constituted on April 2 1941 and consists of senior medical officers with the rank of Lieutenant-Colonel, battalion medical officers who are Majors and under them company and platoon officers with the ranks of Captain and Lieutenant The services of these officers are entirely voluntary and they are appointed by the commanding officers of battalions subject to the approval of the local medical war committee which has to give its certificate that their employment will not prejudice the efficiency of the civilian services In practice the appointment is usually recommended by the senior medical officer or battalion medical officer concerned with the consent of the committee Duties are clearly defined ' the Medical Officer is to be regarded as a Medical Adviser to the Battalion Commanders whose main functions are to arrange the medical facilities within sub-units in accordance with their probable operational needs and to organise and assist in the training of the personnel He is not to be expected to undertake the duties such as are normally carried out by the Regimental Medical Officer of an Infantry Battalion ' The care of Home Guard casualties is the responsibility of local civilian authorities from the moment that they are placed in the ambulances provided by those authorities These ambulances are instructed to collect Home Guard casualties only from points at which they have been assembled by the arrangement of the H G Medical Service Since it is obvious that ambulances may not be available while invasion and attack from the air is actually in progress and that the hospitals to which casualties would normally be sent may be incapable of dealing with them the arrangement of suitable casualty collecting posts is one of the chief duties of the H G medical officer His duties with regard to training are not arduous and he can if he does not feel equal to giving lectures and instructions himself call upon local R A M C units to provide officers for these purposes The most remarkable thing about his duties is that they do not include any form of medical treatment He has to arrange that such treatment will be available and he may in fact if invasion comes have to carry out much of this treatment in his civilian which is medicine He would not be eligible to sit for finals until he had completed 36 months of clinical work, but to keep him mettled up there might be sessional examinations at the medical school At present students are able to sit for part of the finals within 30 months of the second M B, and thus the average student is cramming for a part of the final within 24 months of beginning clinical work This suggested curriculum, admirable as it is, lays emphasis chiefly on groundwork and is not directed towards the special needs of general practice

Students and general practitioners have different suggestions to make On the whole students see more of general practice than do their teachers, many of them are the children of general practitioners and many hear the opinions of recently qualified friends Moreover that concern for social conditions which springs from imaginative appreciation of a neighbour's hardships—socialism in the basic sense—flourishes among the young If we are not willing to put the world right in our early twenties we are poor citizens The British Medical Students Association (p 259) ask that the student should receive better training in preventive medicine and gain more experience of chronic and minor ailments and the simpler gynæcological conditions, that he should have a wider knowledge of public health, of national health insurance, of compensation and rehabilitation They see the general practitioner, in short, as part of the social welfare organisation of the country and would have him competent to undertake that duty Nor are they oblivious of the groundwork on which such training must rest They ask for greater integration in the curriculum, and for orientation courses which would bring the various subjects into proper relationship at the outset One subject in which an orientation course would be particularly valuable is anatomy, a teacher suggests that the whole body might be dissected rapidly before the class, by an expert, before students are allowed to begin on a part All who remember the bewilderment of their first month in the dissecting-room will agree with him Some of the detail might be cut out and he suggests that anatomy should be taught on younger subjects, preferably beginning with the fœtus, so that students may see the organs at various stages of development, not only in the degeneration or atrophy of old age

Not unnaturally, the most practical suggestions for improvement of the curriculum come from general practitioners themselves They would like the student to have free access to the patients in the chronic wards of infirmaries, to see more minor infectious illnesses like tonsillitis, and more minor injuries like sprains They would like him to have personal experience of dispensing, not of writing “rep mist” and leaving the rest to the dispenser, to be confident of giving a safe anæsthetic, to know some practical psychology and more about mental disease and defect, and to realise that there is no mystery about children's diseases or infant feeding They think he should know more about the trifling ills of women—such as vaginal discharge, dysmenorrhœa and menopausal symptoms—and that he should have some instruction about sterility and contraception He should be more adept at recognising the early stages of disease, especially of cancer, and of rheumatic disorders likely to lead to crippling Above all they would have him a competen obstetrician Some would like six months postgraduate work in midwifery to be compulsory fo the general practitioner Others consider that instea of spending a year on general surgery and a mont on midwifery, the periods might well be reversed, or at least more wisely distributed Student spend hours in the theatre watching major surgical and gynæcological procedures which, as general practitioners, they will never perform They enjoy it, naturally, most of us like to assist, in the French sense, while a skilled craftsman does his job, whether it be painting a picture, building a ship, or opening an abdomen But watching major operations is a waste of time in a crowded curriculum, and a scrutiny of the student's timetable would doubtless reveal other extravagances, one doctor reminds us of the time spent loitering in the front hall, awaiting dilatory chiefs Time saved from these and other pursuits might be spent with a good firm of general practitioners Some doctors think the grounding would be adequate if the student attended at such a practice once or twice a week for a month or two, some think he should be resident with the firm for periods ranging from a fortnight to six months, others think this experience could be postgraduate, but none doubts that the person to train another in general practice is the general practitioner This return to the apprenticeship system, they feel, is overdue They do not suggest that it can in any way replace formal clinical teaching, only that it should supplement it, occupying time which can be spared from less essential studies All are emphatic about the value of resident appointments and some would like such postgraduate experience to be compulsory for a man about to enter general practice

The foregoing opinions—whether from teachers, students or practising doctors—are home and Empire produce they are what we can learn from each other But the experience of other countries is also instructive, especially when it forms a comment, spoken or unspoken, on our own practice The accounts of medical education in various parts of the world set out on p 260 will repay study We have something to learn, for example, from the Spanish system of selection, by which the best opportunities go to the best students, from the high standard of general education expected of students in France, from the student discussion groups of Norway, from the German tradition of experience in several universities, from the keenness, diligence and team spirit found in Russian clinics, and from the American principle that medicine deals not with the disease alone but with its effects on the patient, the patient's family and the community Russia, travellers tell us, finds us backward in our treatment of women, Spain thinks the golden age of English medicine is over, Germans are politely astonished when they find an English institution efficiently run, and Americans have to stop and think when they are asked to name the advantages of English medical education It is time to make changes Remembering the old maxim for examination candidates—“do the easy ones first”—let us begin by introducing experience of general practice into the curriculum, and a higher standard of obstetric training among those deciding to become family doctors

The Defence Services

The Central Medical War Committee of the British Medical Association is responsible for the supply of all doctors for the defence services

Royal Naval Medical Service

The usual regulations governing entry of medical and dental officers to the Royal Naval Medical Service are suspended during the war and the only medical officers being admitted are those granted temporary commissions in the Royal Naval Volunteer Reserve After the war any vacancies will probably be filled by selection of officers from among those who have served in the R N V R during the war

Candidates for the Royal Naval Dental Service must be under 28 and registered under the Medical or Dental Acts and must also have a registrable qualification in dental surgery Particulars of conditions of service of naval dental officers can be obtained from the Medical Director-General of the Navy Queen's House, 64, St James's Street London, S W 1

So far only one woman medical officer has been appointed for service in the W R N S She holds the relative rank of a Surgeon Lieutenant, R N V R and serves as medical superintendent attached to the W R N S headquarters at the Admiralty

Royal Army Medical Corps

No applications for regular commissions will be invited during the war for the Royal Army Medical Corps It is expected that after the war regular commissions to make up the establishment of regular officers of the corps will be granted first to those who served as emergency commissioned officers during hostilities All war-time appointments are emergency commissions for the duration of the war, no short-service appointments are being made at present

Home Guard

The Home Guard Medical Service was officially constituted on April 2 1941 and consists of senior medical officers with the rank of Lieutenant-Colonel battalion medical officers who are Majors and under them company and platoon officers with the ranks of Captain and Lieutenant The services of these officers are entirely voluntary and they are appointed by the commanding officers of battalions subject to the approval of the local medical war committee which has to give its certificate that their employment will not prejudice the efficiency of the civilian services In practice the appointment is usually recommended by the senior medical officer or battalion medical officer concerned with the consent of the committee Duties are clearly defined " the Medical Officer is to be regarded as a Medical Adviser to the Battalion Commanders, whose main functions are to arrange the medical facilities within sub-units in accordance with their probable operational needs and to organise and assist in the training of the personnel He is not to be expected to undertake the duties such as are normally carried out by the Regimental Medical Officer of an Infantry Battalion ' The care of Home Guard casualties is the responsibility of local civilian authorities from the moment that they are placed in the ambulances provided by those authorities These ambulances are instructed to collect Home Guard casualties only from points at which they have been assembled by the arrangement of the H G Medical Service Since it is obvious that ambulances may not be available while invasion and attack from the air is actually in progress and that the hospitals to which casualties would normally be sent may be incapable of dealing with them the arrangement of suitable casualty collecting posts is one of the chief duties of the H G medical officer His duties with regard to training are not arduous and he can if he does not feel equal to giving lectures and instructions himself call upon local R A M C units to provide officers for these purposes The most remarkable thing about his duties is that they do not include any form of medical treatment He has to arrange that such treatment will be available and he may in fact if invasion comes, have to carry out much of this treatment in his civilian capacity, but his duties as H G medical officer do not involve his being mobilised for whole-time service and in most cases he has prior obligations to the local authorities or hospitals which would make such service impossible for him All M O 's in the Home Guard are issued with battle dress including forage caps with the badge of the county regiment, their only distinguishing mark is a Red Cross brassard which, it is supposed, would secure to them the protection of the Geneva convention in face of the enemy Entrants must not be over sixty-five years of age and must of course be registered practitioners Although their duties may at first sight appear to be relatively unimportant, it is worth while remembering that no other authority is making arrangements for the disposal of casualties should ambulance traffic be suspended by enemy action

Health Services at Home

EMERGENCY MEDICAL SERVICE

Last year we traced the development of the E M S from the paper scheme drawn up by the Ministry of Health before the war to an actively functioning service London had been divided into its sectors and the rest of the country into regions The hospitals had been classified and affiliated to each other, twelve hospital officers had been appointed to serve the various regions and to work out details of the scheme, and the hospitals in affiliated groups had appointed group officers who planned the distribution of personnel into teams and allocated them to hospitals in the group Rates of pay were

Group officer	£1300
Officer in charge of surgical or medical division (hospital of 500 beds and over)	950
Surgeon or physician specialist	800
Medical officers	550

These rates of pay have remained unchanged, but many consultants, who had suffered serious financial loss by becoming whole-time officers at £800 a year were allowed to become part-time officers at £500 a year and to carry on private practice in their spare time, this plan has been maintained and in addition some consultants have been appointed to serve on a sessional basis The system followed varies in different parts of the country London depends largely on part-time consultants, the provinces more on consultants giving sessional attendance House officers, who at the outset were astonished to find themselves receiving £350 a year, have been reduced to the less spectacular annual salary of £120 for junior housemen and £200 for senior housemen

POOLING

It would be an advantage, of course, if medical personnel could be freely interchangeable between the defence services and the E M S Schemes are now under discussion by the Shakespeare Committee and a considerable degree of pooling has already been achieved The Army and Navy lend the E M S the services of their consultants and senior surgeons, and " command neurologists " are borrowed by the Services from the E M S The bulk of Service patients are treated in E M S hospitals Pooling is only practicable within Great Britain the B E F of course must get all the medical personnel they ask for, and the Navy cannot in the nature of things cooperate very freely in a pooling scheme The R A F share their medical officers as much as possible If invasion should occur, plans for pooling are complete Ambulances, casualty clearing stations, and all the front line services, will be interchangeable Behind these the E M S hospitals will receive all patients Pooling of information is achieved through the M R C committees—on war wounds, shock, burns, peripheral nerve injuries, brain injuries and other conditions—whose findings are at the disposal of all the Services The M R C also has an interservice editorial committee

NEW OPPORTUNITIES FOR STUDENTS

Special centres in the E M S have increased in number and students are finding in them opportunities to gain first-class experience The centres deal with hea injuries, chest injuries, peripheral nerve injuries, fract and neuroses, students have access to all except the for the neuroses The treatment of fractures has advanced at a rate which has achieved, in the past two years, as much as could have been hoped for in ten years of peace At the outbreak of war there were 16 orthopædic centres available and by the beginning of this year they were all full At that time any large influx of casualties would have been accommodated with difficulty, and many patients would necessarily have been sent to centres not equipped to deal with them The Minister of Health, moreover, had decided that the E M S should treat not only war casualties but fractures in miners, munition workers and others engaged in war work Orthopædic personnel was too scarce to allow of fresh orthopædic hospitals being established, instead the E M S set up fracture clinics and fracture departments in hospitals all over the country One experienced surgeon could serve two or three of these centres, which were of three types 56 fracture departments (type A) for long term cases, 200 fracture departments (type B) for ambulant or short term cases, and a large number of fracture clinics (type C) where civilian patients could get massage and supervision as outpatients after leaving hospital Occupational therapy is available in all the orthopædic centres and in the A departments, and all these special departments are open to students

The E M S is gradually arranging convalescent care for all patients, but this has not been easy At the beginning of the war the Red Cross and the Order of St John of Jerusalem set up convalescent homes for Service patients in country houses lent for the purpose Acceptance of civil casualties in such houses is a matter for arrangement between the hospital officer and the commandant of the home, who may be its owner Many of those who willingly lent their homes for the reception of Service casualties have been less enthusiastic about receiving civil defenders, and few are ready to accept convalescent civilian sick But there is evidence that they are beginning to warm to the idea

" A HOME IN THE COUNTRY "

The E M S has encouraged the big teaching schools to adopt a country hospital to which cases can be transferred and at which teaching can be carried on Sometimes this is one of the outlying hospitals, voluntary or municipal, in the sector, and many of the London hospitals had already made such arrangements last year This year more have followed suit and several have moved their teaching centres into the country Now hospitals in Liverpool, Leeds, Cardiff and Birmingham are getting their homes in the country This principle, it is hoped, will be maintained after the war, and it is to the interest of the patients to ensure that large hospitals are not rebuilt in cities but in more healthy surroundings

The E M S authorities have done all they can to help the teaching hospitals to find suitable country quarters and to provide everything needed to make the transfer a success Sometimes the new home has been found in a country house or club and sometimes in a hutted hospital in the grounds of one of the outlying municipal hospitals Those teaching hospitals which can boast a determined dean of the medical school have fared best The E M S authorities are willing to help in every way they can, but they are naturally more inclined to do their best for those who make their needs plainly and repeatedly clear The linkage between the voluntary and the municipal hospitals is growing continually stronger and the student will profit perhaps more than anyone else by such a liaison, for it brings him into contact not only with the rare in medicine but with common and chronic conditions which it will later be his lot to meet daily

Some hospitals in cities have been put completely out of commission by bombing—even to the extent of being reduced to a pile of rubble It has been asked whether such a blitzed hospital can retain its identity If the foundation is rich enough it can survive by transferring the entire hospital to a country home, provided a satisfactory building can be found But few hospitals can afford such removal, and it then becomes the task of the E M S authorities to decide whether in a given case the Government is justified in providing money to maintain a hospital—whether, in short, that particular hospital shall survive. Any hospital which has to do with medical education is likely to be aided at once, but in the case of hospitals without educational or national importance the question is sometimes *difficult to decide*. The fact that the decision rests with the Emergency Hospital Scheme of the Ministry of Health is some indication of the stature to which this infant giant has already grown and foreshadows the issues which will come within the scope of the medical service of the future.

INDUSTRIAL MEDICAL SERVICES

Owing to the Factory (Medical and Welfare Services) Order of the Ministry of Labour (1940) there has been a rapid increase in the number of industrial medical officers appointed to factories within the past year. The Minister of Labour now has power to compel employers to make such appointments, being guided in this matter by the recommendations of the factory inspectorate. Already most of larger firms in the country (those employing 7500 persons or more) have appointed whole-time medical officers. The greatest increase, however, has been in the number of appointments of general practitioners as part-time factory medical officers.

It is estimated that there are approximately 120–150 whole-time doctors employed in factories throughout the country; the number of these may increase before the end of this year but it is unlikely that they will exceed 200 because of the limited number of large industrial organisations. This type of service must be expanded in the future to meet the requirements of smaller firms either by the appointment of an increasing number of part-time medical officers who will mainly be general practitioners, or by the institution of a special industrial medical service in which a doctor gives the whole of his time to industry, but instead of working in one large firm supervises a number of smaller units. There is certainly a gap in the present health services of the country which can be bridged best by appointing doctors whose sphere of work brings them within the factory walls. The needs are three: medical supervision of the first treatment of cases of injury and sickness occurring at work; supervision of the final stages of rehabilitation and of the return to work of sick and injured persons; and a wider knowledge of working conditions on the part of the medical profession generally. Hitherto lack of such knowledge has made it difficult for anyone to prevent ill health caused by industrial environment.

Facilities for training potential and newly appointed industrial medical officers have been provided in a sporadic fashion by weekend courses at the Universities of Birmingham, Manchester and Sheffield, but these facilities might well be improved and increased. Education should link up with research in some coordinated plan if this new branch of medicine is to flourish. The health of the worker has never been more important than it is in these days. The Government are demanding better health and welfare provisions in factories as an essential part of industrial policy; and there is evidence that both employers and workers are becoming increasingly interested in such schemes. Industrial health service will doubtless play a large part in the reconstruction of the health services after the war. The British Medical Association has set up an Industrial Health Committee and information on terms of appointment and conditions of service can be obtained from the Secretary at B M A House, Tavistock Square, London, W C 1.

PRISONS

At the larger prisons whole-time officers are appointed, sometimes with deputy medical officers to assist them. Furnished quarters are provided or an allowance made in aid of rent. Posts are pensionable and promotions are made as vacancies occur. Candidates with a diploma in psychological medicine receive £50 per annum more on appointment than candidates without this qualification, and are given preference provided they also have good all-round general experience. At the smaller prisons no whole-time officers are employed; local practitioners are usually appointed as part-time officers. Further particulars can be obtained from the Prison Commissioners, Oriel College, Oxford.

PUBLIC HEALTH

To the student contemplating a career within the public health services of this country, almost as many varieties of medical service are open as there are in the clinical side of the profession. Originally concerned with problems of sanitation and environmental hygiene the British public health service led the world during the nineteenth century in providing sanitary necessities and in removing some of the worst effects of the industrial revolution. About the beginning of this century its scope was extended to the more personal side of public health with the creation of the school medical, maternity and child welfare, tuberculosis and venereal disease services and all their ancillaries; and later the Local Government Act of 1929 enabled local authorities to take over and improve a vast system of public hospitals, so that at the outbreak of war the beds controlled by public bodies were more than twice the number of those in voluntary hospitals. To the man or woman seeking a hospital or laboratory appointment the differences between service under a local authority or the Emergency Medical Service and in a voluntary hospital are slight and diminishing.

These considerations, however, hardly apply to the student contemplating public health as a specialist career. No medical officer of health may be appointed unless he holds a registered diploma in public health or its equivalent; but once accepted he enjoys security of tenure, in that his removal—like his appointment—must receive the sanction of the Minister of Health. Since the war the number of institutions at which the course of training required for the diploma in public health is available has been somewhat limited.* After obtaining the D P H, an appointment as assistant medical officer of health and school medical officer can, under present conditions, be obtained without difficulty. The duties at this stage are mainly clinical in connexion with the school medical service, maternity and child welfare and specialised clinics of various kinds, or in charge of beds in isolation hospitals. In the counties, the post of assistant medical officer of health is often combined with that of medical officer of health of a county district, which provides an attractive mixture of administrative and public health work. The higher posts are in the main administrative and the medical officer of health of, say, a large county borough, is more in the position of the managing director of an important firm employing several hundreds of technicians than a doctor. The ever-increasing emphasis on preventive medicine enhances the importance and scope of the work of public health departments and medical officers of health.

The war has brought many new public health problems and has depleted the ranks of the public health personnel; though it has been laid down that the public health services of the country must not suffer from excessive recruitment, and machinery exists to prevent too great depletion. Among the new problems may be mentioned the evacuation of children and others to safe areas, which has thrown a strain on the public health staff and sanitary resources of many rural districts and made necessary the extension of schemes for sewerage and water supply; the establishment of temporary hospitals, sick bays and hostels for maternity cases and minor infectious diseases and the expansion of the services already existing; the improvement and supervision of the hygiene of air-raid shelters used as dormitories in target areas; and cooperation with the medical departments of the Forces in matters common to them and the civilian population such as epidemic outbreaks, accommodation of infectious cases, water-supply and sewage disposal in camps. There has also been a large expansion of laboratory facilities under the Ministry of Health's emergency laboratory service; this has put at the disposal of every local authority and E M S hospital a laboratory capable of meeting its needs.

---

* "Very few medical graduates are taking the D P H at present chiefly because the regulations insist on candidates doing a full time appointment as part of the course, and they simply haven't the opportunity at present to do so. This means that there will be an interruption in the flow of those holding the qualification. Would it not be possible during the war to let candidates do a longer part time appointment in place of the full time appointment?" *Extract from a letter*

capacity , but his duties as H G medical officer do not involve his being mobilised for whole-time service and in most cases he has prior obligations to the local authorities or hospitals which would make such service impossible for him All M O 's in the Home Guard are issued with battle dress including forage caps with the badge of the county regiment , their only distinguishing mark is a Red Cross brassard which, it is supposed, would secure to them the protection of the Geneva convention in face of the enemy Entrants must not be over sixty-five years of age and must of course be registered practitioners Although their duties may at first sight appear to be relatively unimportant, it is worth while remembering that no other authority is making arrangements for the disposal of casualties should ambulance traffic be suspended by enemy action

---

Health Services at Home

EMERGENCY MEDICAL SERVICE

Last year we traced the development of the E M S from the paper scheme drawn up by the Ministry of Health before the war to an actively functioning service London had been divided into its sectors and the rest of the country into regions The hospitals had been classified and affiliated to each other , twelve hospital officers had been appointed to serve the various regions and to work out details of the scheme, and the hospitals in affiliated groups had appointed group officers who planned the distribution of personnel into teams and allocated them to hospitals in the group Rates of pay were

Group officer	£1300
Officer in charge of surgical or medical division (hospital of 500 beds and over)	950
Surgeon or physician specialist	800
Medical officers	550

These rates of pay have remained unchanged, but many consultants, who had suffered serious financial loss by becoming whole-time officers at £800 a year were allowed to become part-time officers at £500 a year and to carry on private practice in their spare time , this plan has been maintained and in addition some consultants have been appointed to serve on a sessional basis The system followed varies in different parts of the country London depends largely on part-time consultants, the provinces more on consultants giving sessional attendance House officers, who at the outset were astonished to find themselves receiving £350 a year, have been reduced to the less spectacular annual salary of £120 for junior housemen and £200 for senior housemen

POOLING

It would be an advantage, of course, if medical personnel could be freely interchangeable between the defence services and the E M S Schemes are now under discussion by the Shakespeare Committee and a considerable degree of pooling has already been achieved The Army and Navy lend the E M S the services of their consultants and senior surgeons, and " command neurologists " are borrowed by the Services from the E M S The bulk of Service patients are treated in E M S hospitals Pooling is only practicable within Great Britain the B E F of course must get all the medical personnel they ask for , and the Navy cannot in the nature of things cooperate very freely in a pooling scheme The R A F share their medical officers as much as possible If invasion should occur, plans for pooling are complete Ambulances, casualty clearing stations, and all the front line services, will be interchangeable Behind these the E M S hospitals will receive all patients Pooling of information is achieved through the M R C committees—on war wounds, shock, burns, peripheral nerve injuries, brain injuries and other conditions—whose findings are at the disposal of all the Services The M R C also has an interservice editorial committee

NEW OPPORTUNITIES FOR STUDENTS

Special centres in the E M S have increased in number and students are finding in them opportunities to gain first-class experience The centres deal with injuries, chest injuries, peripheral nerve injuries, fr and neuroses , students have access to all except t for the neuroses The treatment of fractures advanced at a rate which has achieved, in the past years, as much as could have been hoped for in ten of peace At the outbreak of war there were 16 ort pædic centres available and by the beginning of this they were all full At that time any large influx casualties would have been accommodated with culty, and many patients would necessarily have sent to centres not equipped to deal with them Minister of Health, moreover, had decided that E M S should treat not only war casualties but frac in miners, munition workers and others engaged in war work Orthopædic personnel was too scarce to of fresh orthopædic hospitals being established , instead the E M S set up fracture clinics and fracture departments in hospitals all over the country One experienced surgeon could serve two or three of these centres, which were of three types 56 fracture departments (type A) for long term cases , 200 fracture departments (type B) for ambulant or short term cases , and a large number of fracture clinics (type C) where civilian patients could get massage and supervision as outpatients after leaving hospital Occupational therapy is available in all the orthopædic centres and in the A departments , and all these special departments are open to students

The E M S is gradually arranging convalescent care for all patients, but this has not been easy At the beginning of the war the Red Cross and the Order of St John of Jerusalem set up convalescent homes for Service patients in country houses lent for the purpose Acceptance of civil casualties in such houses is a matter for arrangement between the hospital officer and the commandant of the home, who may be its owner Many of those who willingly lent their homes for the reception of Service casualties have been less enthusiastic about receiving civil defenders , and few are ready to accept convalescent civilian sick But there is evidence that they are beginning to warm to the idea

" A HOME IN THE COUNTRY "

The E M S has encouraged the big teaching schools to adopt a country hospital to which cases can be transferred and at which teaching can be carried on Sometimes this is one of the outlying hospitals, voluntary or municipal, in the sector, and many of the London hospitals had already made such arrangements last year This year more have followed suit and several have moved their teaching centres into the country Now hospitals in Liverpool, Leeds, Cardiff and Birmingham are getting their homes in the country This principle, it is hoped, will be maintained after the war, and it is to the interest of the patients to ensure that large hospitals are not rebuilt in cities but in more healthy surroundings

The E M S authorities have done all they can to help the teaching hospitals to find suitable country quarters and to provide everything needed to make the transfer a success Sometimes the new home has been found in a country house or club and sometimes in a hutted hospital in the grounds of one of the outlying municipal hospitals Those teaching hospitals which can boast a determined dean of the medical school have fared best The E M S authorities are willing to help in every way they can, but they are naturally more inclined to do their best for those who make their needs plainly and repeatedly clear The linkage between the voluntary and the municipal hospitals is growing continually stronger and the student will profit perhaps more than anyone else by such a liaison, for it brings him into contact not only with the rare in medicine, but with common and chronic conditions which it will later be his lot to meet daily

Some hospitals in cities have been put completely out of commission by bombing—even to the extent of being reduced to a pile of rubble It has been asked whether such a blitzed hospital can retain its identity If the foundation is rich enough it can survive by transferring the entire hospital to a country home, provided a satisfactory building can be found But few hospitals can afford such removal, and it then becomes the task of the E M S authorities to decide whether in a given case the Government is justified in providing money to maintain hospital—whether, in short, that particular hospital shall survive. Any hospital which has to do with medical education is likely to be aided at once, but in the case of hospitals without educational or national importance the question is sometimes difficult to decide. The fact that the decision rests with the Emergency Hospital Scheme of the Ministry of Health is some indication of the stature to which this infant giant has already grown and foreshadows the issues which will come within the scope of the medical service of the future.

INDUSTRIAL MEDICAL SERVICES

Owing to the Factory (Medical and Welfare Services) Order of the Ministry of Labour (1940) there has been a rapid increase in the number of industrial medical officers appointed to factories within the past year. The Minister of Labour now has power to compel employers to make such appointments, being guided in this matter by the recommendations of the factory inspectorate. Already most of larger firms in the country (those employing 7500 persons or more) have appointed whole-time medical officers. The greatest increase, however, has been in the number of appointments of general practitioners as part-time factory medical officers.

It is estimated that there are approximately 120–150 whole-time doctors employed in factories throughout the country; the number of these may increase before the end of this year but it is unlikely that they will exceed 200 because of the limited number of large industrial organisations. This type of service must be expanded in the future to meet the requirements of smaller firms either by the appointment of an increasing number of part-time medical officers who will mainly be general practitioners, or by the institution of a special industrial medical service in which a doctor gives the whole of his time to industry, but instead of working in one large firm supervises a number of smaller units. There is certainly a gap in the present health services of the country which can be bridged best by appointing doctors whose sphere of work brings them within the factory walls. The needs are three: medical supervision of the first treatment of cases of injury and sickness occurring at work; supervision of the final stages of rehabilitation and of the return to work of sick and injured persons; and a wider knowledge of working conditions on the part of the medical profession generally. Hitherto lack of such knowledge has made it difficult for anyone to prevent ill health caused by industrial environment.

Facilities for training potential and newly appointed industrial medical officers have been provided in a sporadic fashion by weekend courses at the Universities of Birmingham, Manchester and Sheffield, but these facilities might well be improved and increased. LONDON COUNTY COUNCIL HOSPITALS

The hospitals service of the London County Council provides not only special facilities for undergraduate instruction, but also opportunities for valuable experience for medical graduates who intend either to be general practitioners or consultants, or to make the Public Health and Hospital Service their career At the beginning of the war, the service, one of the most comprehensive hospital services in the world, contained 97 hospitals with beds for 71 694 patients The 97 hospitals consist of 44 general hospitals, 32 special hospitals and 21 mental hospitals and institutions for the mentally defective , 54 of the hospitals are included in the Emergency Hospital Scheme

Treatment is provided in these hospitals for all kinds of acute and chronic illnesses, including fevers, tuberculosis, mental and nervous disorders

HOSPITALS BRANCH

Medical superintendents of the hospitals, who are expected to be experienced hospital administrators, receive £850 to £1650 a year, in hospitals varying in accommodation from 160 to 1300 patients In addition, medical superintendents are provided with an unfurnished house or quarters with payment by the Council of local and water rates The other full-time medical staff are classified as follows

Grade	*Annual salary*
Deputy medical superintendent, class I	£650—£50—£800
Deputy medical superintendent, class II	£600—£30—£750
Deputy medical superintendent, class III	£550—£25—£650
Deputy medical superintendent, class IV	£500—£25—£600
Senior resident surgeon physician, or obstetrician, and senior assistant medical officer	£500—£25—£600
Assistant medical officer, class I	£350—£25—£425
Assistant medical officer class II	£250
House physicians and house surgeons	£120

These officers are provided with board, lodging and washing Clinical assistants, who are non-resident, receive £150 a year with meals when on duty Vacancies in the higher grades are filled as far as possible by promotion from the existing staff In addition, a large number of part-time consultants and specialists are employed in the various hospitals and the establishment provides for a certain number of whole-time non-resident specialists at a salary of £1250—£50—£1500

There was some disorganisation of the consultant service at the outbreak of war, but by February, 1940, it was again working normally, though with reduced numbers of sessions A comprehensive pathological service has been established There are seven group laboratories, each of which serves a number of hospitals, a central histological laboratory, and an antitoxin establishment Attached to the group laboratories are subsidiary laboratories situated in the various hospitals Normally a medical staff of 27 is attached to these laboratories, but some of them are at present working at other laboratories under the E M S

TEACHING FACILITIES

During the war, courses for the diploma in public health are held in the council's hospitals , other postgraduate facilities have remained as they were The British Postgraduate School is located in the Council's Hammersmith Hospital

Patients under treatment in the Council's hospitals have not been much reduced in number and increased use is being made of them for teaching purposes Maternity wards of many of the voluntary hospitals have been closed, and arrangements have been made whereby maternity students have had training and experience in the maternity departments of the Council's general hospitals Most of the students are resident and attend for a fortnight at a time In addition, students have been allocated to a number of the general and special hospitals under the Emergency Medical Scheme to act as dressers The Council has agreed that medical training and experience shall be provided whenever possible , in most cases the students, some of whom are resident, receive systematic instruction from the resident medical staff of the hospital The fever hospitals provide special facilities for undergraduate instruction, and when patients are available, for demonstrations in the diagnosis and treatment of smallpox for both undergraduate and postgraduate students

Most of the general hospitals are recognised training centres for candidates for the University of London M D examination , 18 of them for the Diploma and Membership of the Royal College of Obstetricians and Gynæcologists and for the final F R C S examination and the Diploma in Anæsthetics Service at Queen Mary's Hospital for Children, Carshalton, is recognised by the Royal Colleges of Physicians and Surgeons as a part qualification for the Diploma in Child Health

MENTAL HOSPITALS BRANCH

The mental health services of the L C C are responsible for a large medical service, vacancies in which are normally advertised at short intervals No new permanent appointments are being made at present, indeed the staffs of the various hospitals have been reduced as a war measure In peace-time those appointed to the service may be sent to any of the Council's mental hospitals and may be transferred from one hospital to another should circumstances require it An applicant enters the service as assistant medical officer at a salary of £470 a year, rising by annual increments of £25 to £570 Salaries are graded through the various ranks to £1450 paid to superintendents of large hospitals , a superintendent is also provided with an unfurnished house on the hospital premises Assistant medical officers may be required to live in the institution which they are serving and to pay fixed rates for board, lodging and washing Officers contribute to a superannuation fund They are required to take a Diploma in Psychological Medicine within three years of entering the service and the diploma carries with it a payment, in addition to salary, of £50 a year Promotion is reasonably rapid for men The mental health services are actively concerned in the E M S. Three hospitals are used entirely as emergency hospitals and at eight others there is an emergency hospital section Treatment is provided for all types of acute, medical and surgical cases and the hospitals are staffed and equipped to give specialised treatment The medical staff for these hospitals is drawn mainly from the emergency medical service

MENTAL HOSPITALS OUTSIDE THE LONDON AREA

Posts for medical officers in the provinces are similar in scope and remuneration to those in London They are advertised regularly in the medical journals

Services Abroad

INDIAN MEDICAL SERVICE

Recruitment to the Indian Medical Service, which is designed primarily to meet the needs of the Indian Army, has been modified by the war, and officers are now appointed to emergency commissions in the military branch for the duration of the war A large number of emergency commissioned officers are required at present, and the appointments are particularly suitable for young doctors who wish to serve in India Officers who have held such commissions will, if qualified under the conditions then in force, be given preference when the grant of permanent commissions is resumed after the war The age-limit for emergency commissions has been raised from 32 to 45 An antedate may be granted on appointment to an officer who has held an approved whole-time appointment in a recognised civil hospital or who possesses higher qualifications and professional experience All previous full pay commissioned service with the armed forces as a medical officer counts towards rank and seniority Appointment carries a free passage to India for the officer and an allowance for uniform, but if qualified and selected for a specialist post an emergency commissioned officer will be given the appropriate temporary rank with pay and allowances for the appointment Passages are not granted to wives and families resident out of India when the officer is selected for the grant of an emergency commission, unless, on the termination of his service, the officer elects to reside in India, when conveyance to the selected place of residence in India is admissible

The pay of a European lieutenant in India is £585 per annum, and of a captain £750 per annum on promotion , on his release an emergency commissioned officer receives a gratuity at the rate of one month's pay for each year of Army service If invalided out for a disability due to service he receives retired pay appropriate to his rank and degree of disablement If he dies as a result of military service during the war, provision is made for his widow and children Full information about the conditions of service may be obtained from the Military Secretary, India Office, 4 Central Buildings London, S W 1 The Medical Adviser to the Secretary of State for India India Office, Whitehall, is always willing to interview prospective officers

WOMEN'S MEDICAL SERVICE FOR INDIA

Admission to the service is by selection in India and England, preference being given to women with Indian experience , appointment is open to English and Indian qualified women and the number of full medical officers is 44 There are 6–10 temporary officers and a training reserve of about 14 recently qualified women from Indian universities Vacancies are few, usually only three or four in each year, and there is little recruitment from England Since the outbreak of war no members of the training reserve have been sent to England for postgraduate study Leave out of India has also been restricted and vacancies in the service are being filled by doctors in India as need arises The office of the Dufferin Association in London is closed for the duration of the war, and the post of medical adviser is in abeyance Those seeking information about the Association should apply to the High Commissioner for India, India House, Aldwych London, W C 2

COLONIAL MEDICAL SERVICE

The Colonial Office is anxious that young doctors should realise that recruitment for the Colonial Medical Service at the present time has been officially approved and that service in the Colonial Empire is of as much national importance as service in the Forces Vacancies occur most frequently in tropical Africa and Malaya Specialist appointments are usually reserved for officers already in the service who have shown outstanding merit in a particular branch A few vacancies may occur for women with experience in maternity and child welfare work Selected candidates are generally required to attend a course in tropical medicine and hygiene before going overseas or during their first leave period The colonial empire covers about 2,000 000 square miles and contains a population of over 60 millions The various Government medical departments employ about 700 European medical officers, including some 30 women and about the same number of locally appointed medical officers Medical experience may include—among other diseases associated with the tropics—malaria yaws, leprosy sleeping sickness, plague yellow fever cholera, as well as the common diseases of medical practice An officer in the Colonial Medical Service has special opportunities for the practice of his profession in preventive medicine as well as in other branches, there are also opportunities for research Full particulars of the terms and conditions of service may be obtained from the Director of Recruitment (Colonial Service), Colonial Office, 29, Queen Anne's Gate, London, S W 1

SUDAN MEDICAL SERVICE

This service is responsible for civil medical and public health work in the Sudan, and for the health of the Sudan Defence Force Recruitment has ceased for the time being but it is possible that it will be resumed before the end of this year Those seeking further particulars should write to the Consulting Physician to the Sudan Government, 93, Harley Street, London, W 1

SOUTHERN RHODESIAN MEDICAL SERVICE

The Government maintains a medical and public health service in which whole-time and part-time officers are employed Full particulars may be obtained from the High Commissioner for Southern Rhodesia, 429, Strand, London, W C 2

B M A AND B H A —The British Medical Association and the British Hospitals Association have set up a liaison committee to meet when required to discuss subjects of mutual interest The committee will consist of three representatives from each association

BRITISH MEDICAL STUDENTS ASSOCIATION

THE National Union of Students includes students from all faculties Before the war a medical subcommittee existed chiefly to organise pleasant but rather extravagant meetings , and when war broke out this committee was disbanded on grounds of expense At that time medical students particularly those in London were experiencing the effects on teaching of the first dispersal of patients and medical schools Dislocation of their work led them to form the London Medical Committee to which most of the London schools sent delegates This committee drew up schemes for emergency training and for the utilisation of preclinical students in civil defence and in a number of hospitals the schemes were adopted

Realising that the problems of London students were likely to be shared by students in the provinces the committee called a conference in Manchester in May 1940 to which delegates from all medical schools were invited Nineteen schools—nearly two-thirds of the total—were represented At this meeting the British Medical Students Association was founded Later a pamphlet (" B M S A —the Plan ") was issued in which the aims of the association were set out It was proposed that a national scheme for medical students should be put into operation under the Ministry of Health and other responsible bodies by which teaching facilities and clinical opportunities might be fairly shared and financial loss—due to evacuation billeting and travelling costs—be compensated by the Ministry The curriculum was also discussed the following principles gaining general support ability to use knowledge being the basis of education there should be a preliminary cultural and scientific background , the subjects of medical training must form an interrelated whole , staff and students should be represented on curriculum committees to plan orientation of teaching and teachers should be selected for their ability to teach rather than their experience as specialists or research workers It was also felt that discussion groups should replace formal lectures that medicine should be taught with greater emphasis on its social aspects and that there should be a single national qualification conducted by a central medical authority

Those who had been hoping for a united medical student movement were largely disappointed but with the onset of heavy bombing the need for an active organisation became more pressing and thanks to the energy of a small group of students chiefly from Manchester a large meeting of the B M S A was held at the N U S congress at Cambridge in April 1941 The proceedings were reported in our columns [1] Some of the original aims were reaffirmed—for example there was still a general demand for greater integration of training for orientation courses especially as an introduction to general biology , and for a curriculum which gave more attention to social medicine There was also a desire for more emphasis on common and minor ailments such as provide the bulk of the work in general practice for much more training in preventive medicine and for greater knowledge of public health machinery and of insurance compensation and rehabilitation Student health and health insurance schemes were discussed

Since that conference the B M S A has been invited by the Medical Planning Commission of the British Medical Association to prepare a memorandum on medical education This was discussed at a council meeting at Cambridge in July only ten of the thirty-odd medical schools in England Wales and Scotland sent delegates and it was felt that not even the broad principles of a memorandum representative of student opinion could be attempted at that stage A committee of three—two men and one woman—was therefore appointed to invite the views of all medical schools and an outline for discussion was drawn up The committee asks that every school whatever its relations with the N U S or the B M S A should take a full part in helping to draw up this memorandum Students who have individual suggestions to offer or who wish to criticise the existing curriculum should send their views to Mr K C Willett Middlesex Hospital London W 1

LONDON COUNTY COUNCIL HOSPITALS

The hospitals service of the London County Council provides *not only special facilities for undergraduate* instruction, but also opportunities for valuable experience for medical graduates who intend either to be general practitioners or consultants, or to make the Public Health and Hospital Service their career At the beginning of the war, the service, one of the most comprehensive hospital services in the world, contained 97 hospitals with beds for 71 694 patients The 97 hospitals consist of 44 general hospitals, 32 special hospitals *and 21 mental hospitals and institutions for* the mentally defective, 54 of the hospitals are included in the Emergency Hospital Scheme

Treatment is provided in these hospitals for all kinds of acute and chronic illnesses, including fevers, tuberculosis, mental and nervous disorders

HOSPITALS BRANCH

Medical superintendents of the hospitals who are expected to be experienced hospital administrators, receive £850 to £1650 a year, in hospitals varying in accommodation from 160 to 1300 patients In addition, medical superintendents are provided with an unfurnished house or quarters with payment by the Council of local and water rates The other full-time medical staff are classified as follows

Grade	*Annual salary*
Deputy medical superintendent, class I	£650—£50—£800
Deputy medical superintendent, class II	£600—£30—£750
Deputy medical superintendent, class III	£550—£25—£650
Deputy medical superintendent, class IV	£500—£25—£600
Senior resident surgeon physician, or obstetrician, and senior assistant medical officer	£500—£25—£600
Assistant medical officer, class I	£350—£25—£425
Assistant medical officer, class II	£250
House physicians and house surgeons	£120

These officers are provided with board, lodging and washing Clinical assistants, who are non-resident, receive £150 a year with meals when on duty Vacancies in the higher grades are filled as far as possible by promotion from the existing staff In addition a large number of part-time consultants and specialists are employed in the various hospitals and the establishment *provides for a certain number of whole-time non-resident* specialists at a salary of £1250—£50—£1500

There was some disorganisation of the consultant service at the outbreak of war, but by February, 1940, it was again working normally, though with reduced numbers of sessions A comprehensive pathological service has been established There are seven group laboratories, each of which serves a number of hospitals, a central histological laboratory, and an antitoxin establishment Attached to the group laboratories are subsidiary laboratories situated in the various hospitals Normally a medical staff of 27 is attached to these laboratories, but some of them are at present working at other laboratories under the E M S

TEACHING FACILITIES

During the war, courses for the diploma in public health are held in the council's hospitals, other postgraduate facilities have remained as they were The British Postgraduate School is located in the Council's Hammersmith Hospital

Patients under treatment in the Council's hospitals have not been much reduced in number, and increased *use is being made of them for teaching purposes* Maternity wards of many of the voluntary hospitals have been closed, and arrangements have been made whereby maternity students have had training and experience in the maternity departments of the Council's general hospitals Most of the students are resident and attend for a fortnight at a time In addition, students have been allocated to a number of the general and special hospitals under the Emergency Medical Scheme to act as dressers The Council has agreed that medical training and experience shall be provided whenever possible, in most cases the students, some of whom are resident, receive systematic instruction from the resident medical staff of the hospital The fever hospitals provide special facilities *for undergraduate instruction*, and when patients are available, for demonstrations in the diagnosis and treatment of smallpox for both undergraduate and postgraduate students

Most of the general hospitals are recognised training centres for candidates for the University of London M D examination, 18 of them for the Diploma and Membership of the Royal College of Obstetricians and Gynæcologists and for the final F R C S examination and the Diploma in Anæsthetics Service at Queen Mary's Hospital for Children, Carshalton, is recognised by the Royal Colleges of Physicians and Surgeons as a part qualification for the Diploma in Child Health

MENTAL HOSPITALS BRANCH

The mental health services of the L C C are responsible for a large medical service, vacancies in which are normally advertised at short intervals No new permanent appointments are being made at present, indeed the staffs of the various hospitals have been reduced *as a war measure In peace time those appointed* to the service may be sent to any of the Council's mental hospitals and may be transferred from one hospital to another should circumstances require it An applicant enters the service as assistant medical officer at a salary of £470 a year, rising by annual increments of £25 to £570 Salaries are graded through the various ranks to £1450 paid to superintendents of large hospitals, a superintendent is also provided with an unfurnished house on the hospital premises Assistant medical officers may be required to live in the institution which they are serving and to pay fixed rates for board, lodging and washing Officers contribute to a superannuation fund They are required to take a *Diploma* in Psychological Medicine within three years of entering the service and the diploma carries with it a payment, in addition to salary, of £50 a year Promotion is reasonably rapid for men The mental health services are actively concerned in the E M S, Three hospitals are used entirely as emergency hospitals and at eight others there is an emergency hospital section Treatment is provided for all types of acute, medical and surgical cases and the hospitals are staffed and equipped to give specialised treatment The medical staff for these hospitals is drawn mainly from the emergency medical service

MENTAL HOSPITALS OUTSIDE THE LONDON AREA

Posts for medical officers in the provinces are similar in scope and remuneration to those in London They are advertised regularly in the medical journals

---

Services Abroad

INDIAN MEDICAL SERVICE

Recruitment to the Indian Medical Service, which is designed primarily to meet the needs of the Indian Army, has been modified by the war, and officers are now appointed to emergency commissions in the military branch for the duration of the war A large number of emergency commissioned officers are required at present, and the appointments are particularly suitable for young doctors who wish to serve in India Officers who have held such commissions will, if qualified under the conditions then in force, be given preference when the grant of permanent commissions is resumed after the war The age-limit for emergency commissions has been raised from 32 to 45 An antedate may be granted on appointment to an officer who has held an approved *whole-time appointment* in a recognised civil hospital or who possesses higher qualifications and professional experience All previous full pay commissioned service with the armed forces as a medical officer counts towards rank and seniority Appointment carries a free passage to India for the officer and an allowance *for uniform*, but if qualified and selected for a specialist post an emergency commissioned officer will be given the appropriate temporary rank with pay and allowances for the appointment Passages are not granted to wives and families resident out of India when the officer is selected for the grant of an emergency commission, unless, on the termination of his service, the officer elects to reside in India, when conveyance to the selected place of residence in India is admissible

The pay of a European lieutenant in India is £585 per annum, and of a captain £750 per annum on promotion, on his release an emergency commissioned officer receives the most successful of its students to fill its resident posts , the appointments are for a year and during this time four months are spent on medicine four months on surgery, and four months on casualty or some specialty like anæsthesia All men fortunate enough to get a hospital appointment are thus given a wide experience without the necessity for spending too much time at it, or the recurrent bother of searching for a new job every six months At the end of the year registrars are chosen from the residents for a further year and the unsuccessful may pass on to appointments at special hospitals, such as those for women and children

The distances between towns in Australia made it imperative formerly, that every man should have a reasonable training in operative surgery This was certainly so before 1930 when a house-surgeon was expected to do operations a registrar would be grateful for now Distance however is being annihilated and so the necessity for such a high general standard is diminishing A more important influence has been the rise of the Royal College of Surgeons of Australasia The last war brought many Australian doctors to France and on demobilisation many of them stayed on in England and took the F R C S If this led to a rather narrow prejudice against the Edinburgh Fellowship, it also stimulated those who returned to improve surgical training and status in Australasia This has meant the limitation of the training of the many in order that the few might be better trained, and was met with some criticism at first The relationship to medical education of the College of Surgeons, and of the newly founded College of Medicine, is now settling to that of the English model This trend brings the deeper aims of the profession in Australia still more in line with those of the country from which it sprung, and guarantees that the standards of the past will be steadily raised Australian medical education can well bear comparison with the best available elsewhere, as the increasing number of her notable medical men bears witness

NEW ZEALAND

New Zealand has one medical school at the University of Otago in Dunedin The yearly admission of students fluctuates between 40 and 100 Teaching and hospital work are carried on for three terms in every year, a term lasting 12–13 weeks, and professional examinations conform roughly to the pattern of those in the Scottish schools, from which the New Zealand tradition derives The first year is spent on physics, chemistry and biology, the second and third years on anatomy and physiology Pathology, bacteriology, and materia medica are studied in the fourth year, at the end of which there is a professional examination in those subjects At the same time lectures in medicine and surgery are given, and the student works in the wards of the Dunedin Hospital In the fifth year he continues his course in medicine, and has classes and clinical work in obstetrics and gynæcology and in the usual special subjects, as well as short courses preparing him for part I of the final examination at the end of the year this consists of public health and medical jurisprudence together with an examination in applied anatomy and applied physiology That concludes the formal part of the student's training In the sixth or final year, the class is divided into four groups, one of which works in each of the country's four large general hospitals (Auckland, Wellington Christchurch and Dunedin) There the student makes a complete round of the wards and departments, medical, surgical and special, spending about six weeks in each , he studies the patients, assists the house-physicians and house surgeons in minor procedures and receives clinical teaching from the members of the honorary staff The four hospitals contain over 2000 beds among them At the end of that clinical year the student returns to Dunedin for part II of his final examination (medicine surgery, obstetrics and gynæcology), the passing of which gives him the M B , Ch B degree of the University of New Zealand There is little organised postgraduate teaching, but before the war 30–50% of New Zealand students came to England or Scotland within a year or two of graduation for postgraduate experience and higher qualifications, and a smaller number were beginning to seek the same advantages in Australia

MEDICAL EDUCATION IN THE UNITED STATES

Medical students beginning anatomy and physiology in American schools must have done a minimum of two years' university work which includes prescribed courses in physics, chemistry and biology Some medical schools require three years' work and some a baccalaureate degree, and in practice nearly all students taking up medicine are university graduates who have been four years at college, have taken a degree in the premedical sciences and have reached the age of twenty-two They study for a further four years beginning with an intensive course in anatomy, physiology, pharmacology, pathology, bacteriology and biochemistry lasting through the first two years Though they do not ordinarily start clinical work until their second year in some schools they attend clinical demonstrations given by the most able of their teachers during the first year Set lectures become fewer as they go on At Harvard during their early years no official lecture courses may be fixed for Tuesday, Thursday and Saturday afternoons, though lectures at which attendance is optional and no credit given may be scheduled on those days About 30% of students use the free afternoons for research , their professors advise and encourage them, but the work done is their own affair In the third year of training there is only one lecture a day—often at 8 30 in the morning—and in the fourth year none Clinical classes in small groups are common however, and students and teachers often meet for informal discussion in the evening, learning at such gatherings to know each other well Few fail to do a year or two as interns after qualifying and those who intend to specialise subsequently take resident posts or appointments as registrars just as they would in England

Graduation from medical school does not give the right to practise The graduate must also pass the state examinations to those states in which he wishes to work, or a national examination which qualifies him to practise in any state There is a growing tendency for all students to take the national examination About five years ago examining boards to certify qualification in the various specialties were organised within the profession itself , these boards have gained strength and are now able to insist on an appropriate standard of experience and training among examination candidates who intend to specialise There are 77 medical schools in the United States and all except three are recognised as reaching class A This high standard has been achieved in the last generation , the Carnegie Foundation drew attention to defects in the medical schools at the beginning of this century and the American Medical Association undertook the task of raising the standard by establishing a system of inspection and control through their Council on Medical Education

Teaching of Preventive Medicine —About a quarter of the schools have a full-time department of preventive medicine and the great majority give organised instruction Where independent departments do not exist this is usually done in connexion with the department of bacteriology, often termed the department of bacteriology and preventive medicine In a number of schools this subject is taught throughout the four years of medical training The view is taken that every doctor must practise preventive medicine , and that those who wish to specialise in it will go into the public health service The whole medical course is built on the study of the three directions in which disease can act , on the patient, on the patient's family and on the society in which the patient lives Thus the problem of disease is treated as a group problem Newcomers to the medical school at Harvard are taken on their first day to the Peter Bent Brigham Hospital where they are actually shown a patient—a revolutionary step on the first day of medical training The professor explains the case as he might explain it to intelligent laymen , and having discussed the disease, shows how it has affected the patient, his family and the community Thus from their first lecture students grasp the principle that medicine must be approached from these three aspects , and their subsequent education insists on that principle again and again In their fourth year of training, when they are responsible for cases of their own, they are expected to go to the patient's home, to the office or factory where he works

Grand Tour

MEDICAL EDUCATION IN THE DOMINIONS

SOUTH AFRICA

Fully trained graduates of medicine first emerged from the Universities of Cape Town and Johannesburg little more than twenty years ago They showed a high standard of training, served the people of South Africa with enthusiasm and keenness, and are now in many instances holding posts of distinction in England and other countries Thus it proved that a long tradition was not essential to a medical school a new school even had advantages The men who shaped its course came from different schools, and different lands with varying ideas and practice, they were in a position to choose the best and avoid the mistakes of others

The South African medical degree can only be taken at a university—there are no colleges It takes six years, half of which are spent in the wards The student completes his anatomy and physiology by the end of his second year, and though the time spent on anatomy is a little short compared with the time the older surgeons spent on it, it is a sound full course, and extended in the third year by the study of embryology and anthropology During his courses in bacteriology, pathology and pharmacology the student is not able to undertake any serious study of clinical cases lectures and laboratory work make too many demands on his time, but since he is by now hankering for "real doctoring," it might be an advantage if he had the opportunity of attending demonstrations on well-known diseases during this period of training

In the wards the South African student has the benefit of more or less individual coaching in clinical material from junior consultants appointed as registrars Thus his methods of physical examination can be checked frequent discussions preserve him from the tendency to diagnose the occasional rather than the common, and he can be taught the technique of minor operations The registrars are also stimulated by constant teaching to study medical literature and to be precise in examination and diagnosis The student spends a whole year on surgery, followed by a whole year on medicine, in his final year he does both This enables him to attend a full and systematic course of lectures, and to concentrate on reading the textbooks of one subject at a time, it does perhaps lead him to separate medicine and surgery into watertight compartments however Yet the abundance of clinical material in the exceptionally large hospitals attached to the South African universities does much to restore the balance and to give the student the chance to see medicine as a whole

In both universities the system of co-education works handsomely, despite the prejudice against it in some of the London medical schools All South African hospitals provide ample accommodation for women doctors and students They have also recognised the importance of providing good quarters for students In England and elsewhere students often have to live in grimy squalid lodgings near the hospital, which is often situated in a slum area, neither the company nor the atmosphere is good for their health In South Africa large hostels have been built, and these are supervised by the professorial staffs It is recognised that the doctor plays an important rôle in educating the public, and his own education must therefore be a generous one To live among different groups of men, to see, hear and discuss their views is the best way to acquire a broad view of life It might be a good plan to arrange short vacation visits for students from one university to the other, so that they could gain new friends and encounter new teachers and fresh ideas

The South African Government is alive to the importance of its public health services Large tuberculosis hospitals are being established and the problem of venereal disease among the natives is being tackled The white population of South Africa is a limited one and the government has therefore realised the importance of training, for the coloured and the native populations, their own doctors, nurses, midwives and ord Special hospitals have been set aside for this pu There will be much work for the doctor in the c years The Workmen's Compensation Act an increased wage-earning capacity of coloured w brings them within the scope of private and spec medical practice The field of specialist pract protected by a committee which allows no-one to pr as a specialist unless he has been approved graduate educational demands are already being and before the war there were regular refresher c at both universities for medical officers practising country districts It is perhaps not too much to ho the whole-time professorial units, envisaged by Nuffield, in which the professor and his assistant devote their time to the students We may look for the interchange of registrars and lecturers bet countries, which had been begun before the war bet England, America and Canada Now is the tin dream and plan for such things

AUSTRALIA

When this war broke out, a balance between supply and demand had just been reached an Australia's doctors after the disturbances of the last The present crisis will hardly affect medical educ in Australia as much as the last one, and any cha are likely to be gradual, conforming to those w have proved successful elsewhere Medical educa is in the hands of young and progressive men th and of recent years minor alterations to the cu ulum have betokened dissatisfaction with pres methods The New Zealand experiment, if success will not be without influence, while any changes m in England are bound to have their reflection Australia

Australians have been described as half-way betw Americans and Englishmen, and a superficial obse might make the same generalisation about their mec faculty Closer examination shows that resemblanc the American schools is skin deep, and comes from organisation of a university and medical faculty sid side in the large cities The design of hospitals, anat schools, and affiliated institutions—unhampered as are by any restrictions of space or need to con to existing buildings—does remind one of America smaller scale The medical needs of the populatio 7½ millions are served by four medical schools in cities of Sydney, Melbourne, Adelaide and Brisb the last being the most recently established Preme subjects may be taken in the universities of Hobart Perth, the second-year course being continued in o the larger universities The subjects of the c correspond in all essentials with the English curricu Second and third years are spent entirely at the unive in the study of anatomy, physiology, bacteriology biochemistry Clinical training begins in the f year, with the appropriate resident periods for cas dressers and midwifery students Association with university is maintained, during these years, by central teaching of pathology, public health, su anatomy, materia medica, and kindred subjects E nations being under the control of the university in city, only one qualification—M B, B S —can be obta it is also the only degree which can be registered, makes for simplicity and uniformity The close ass tion of university and hospital has been encouraged in all four universities at least one hospital is to be f in the university grounds or just beside them Hosp are chosen by students largely on a sectarian basis as there is no overcrowding of the courses there a disappointments Association with the universi close throughout training, and hospital loyalties thus subject to the more unifying influence of lo to a university

Final examinations correspond to the unive examinations here The three final subjects, medi surgery, and obstetrics and gynæcology, must be pass one sitting, however, a "sitting" includes a su mentary examination, which can be taken in one su provided the candidate has been successful in the two The varied clinical material available scope for sound practical training, which is cont in the hospital appointments Each hospital take the most successful of its students to fill its resident posts . the appointments are for a year and during this time four months are spent on medicine four months on surgery, and four months on casualty or some specialty like anæsthesia All men fortunate enough to get a hospital appointment are thus given a wide experience without the necessity for spending too much time at it, or the recurrent bother of searching for a new job every six months At the end of the year registrars are chosen from the residents for a further year and the unsuccessful may pass on to appointments at special hospitals such as those for women and children

The distances between towns in Australia made it imperative formerly that every man should have a reasonable training in operative surgery This was certainly so before 1930 when a house-surgeon was expected to do operations a registrar would be grateful for now Distance however is being annihilated and so the necessity for such a high general standard is diminishing A more important influence has been the rise of the Royal College of Surgeons of Australasia The last war brought many Australian doctors to France and on demobilisation many of them stayed on in England and took the F R C S If this led to a rather narrow prejudice against the Edinburgh Fellowship it also stimulated those who returned to improve surgical training and status in Australasia This has meant the limitation of the training of the many in order that the few might be better trained and was met with some criticism at first The relationship to medical education of the College of Surgeons and of the newly founded College of Medicine is now settling to that of the English model This trend brings the deeper aims of the profession in Australia still more in line with those of the country from which it sprung and guarantees that the standards of the past will be steadily raised Australian medical education can well bear comparison with the best available elsewhere, as the increasing number of her notable medical men bears witness

NEW ZEALAND

New Zealand has one medical school, at the University of Otago in Dunedin The yearly admission of students fluctuates between 40 and 100 Teaching and hospital work are carried on for three terms in every year, a term lasting 12–13 weeks and professional examinations conform roughly to the pattern of those in the Scottish schools from which the New Zealand tradition derives e first year is spent on physics chemistry and biology e second and third years on anatomy and physiology thology bacteriology, and materia medica are studied the fourth year, at the end of which there is a prosional examination in those subjects At the same ie lectures in medicine and surgery are given, and the ident works in the wards of the Dunedin Hospital the fifth year he continues his course in medicine and s classes and clinical work in obstetrics and gynæcology d in the usual special subjects as well as short courses eparing him for part I of the final examination at the d of the year this consists of public health and edical jurisprudence together with an examination applied anatomy and applied physiology That ncludes the formal part of the student's training the sixth or final year, the class is divided into four oups, one of which works in each of the country s four rge general hospitals (Auckland, Wellington Christurch and Dunedin) There the student makes a mplete round of the wards and departments medical, rgical and special, spending about six weeks in each , studies the patients, assists the house-physicians and ouse-surgeons in minor procedures and receives inical teaching from the members of the honorary aff The four hospitals contain over 2000 beds among iem At the end of that clinical year the student eturns to Dunedin for part II of his final examination nedicine surgery, obstetrics and gynæcology) the assing of which gives him the M B Ch B degree of the niversity of New Zealand There is little organised ostgraduate teaching but before the war 30–50% f New Zealand students came to England or Scotland ithin a year or two of graduation for postgraduate xperience and higher qualifications and a smaller umber were beginning to seek the same advantages in ustralia

MEDICAL EDUCATION IN THE UNITED STATES

Medical students beginning anatomy and physiology in American schools must have done a minimum of two years university work which includes prescribed courses in physics chemistry and biology Some medical schools require three years work and some a baccalaureate degree and in practice nearly all students taking up medicine are university graduates who have been four years at college have taken a degree in the premedical sciences and have reached the age of twenty-two They study for a further four years beginning with an intensive course in anatomy physiology, pharmacology pathology bacteriology and biochemistry lasting through the first two years Though they do not ordinarily start clinical work until their second year in some schools they attend clinical demonstrations given by the most able of their teachers during the first year Set lectures become fewer as they go on At Harvard during their early years no official lecture courses may be fixed for Tuesday Thursday and Saturday afternoons though lectures at which attendance is optional and no credit given may be scheduled on those days About 30% of students use the free afternoons for research their professors advise and encourage them, but the work done is their own affair In the third year of training there is only one lecture a day—often at 8 30 in the morning—and in the fourth year none Clinical classes in small groups are common however and students and teachers often meet for informal discussion in the evening, learning at such gatherings to know each other well Few fail to do a year or two as interns after qualifying and those who intend to specialise subsequently take resident posts or appointments as registrars just as they would in England

AUSTRALIA

When this war broke out, a balance between the supply and demand had just been reached among Australia's doctors after the disturbances of the last war The present crisis will hardly affect medical education in Australia as much as the last one, and any changes are likely to be gradual, conforming to those which have proved successful elsewhere Medical education is in the hands of young and progressive men there, and of recent years minor alterations to the curriculum have betokened dissatisfaction with present methods The New Zealand experiment, if successful, will not be without influence, while any changes made in England are bound to have their reflection in Australia

Australians have been described as half-way between Americans and Englishmen and a superficial observer might make the same generalisation about their medical faculty Closer examination shows that resemblance to the American schools is skin deep, and comes from the organisation of a university and medical faculty side by side in the large cities The design of hospitals, anatomy schools, and affiliated institutions—unhampered as they are by any restrictions of space or need to conform to existing buildings—does remind one of America on a smaller scale The medical needs of the population of 7½ millions are served by four medical schools in the cities of Sydney, Melbourne, Adelaide and Brisbane, the last being the most recently established Premedical subjects may be taken in the universities of Hobart and Perth, the second-year course being continued in one of the larger universities The subjects of the course correspond in all essentials with the English curriculum Second and third years are spent entirely at the university in the study of anatomy, physiology, bacteriology and biochemistry Clinical training begins in the fourth year, with the appropriate resident periods for casualty dressers and midwifery students Association with the university is maintained, during these years, by the central teaching of pathology, public health, surgical anatomy, materia medica, and kindred subjects Examinations being under the control of the university in each city, only one qualification—M B, B S—can be obtained it is also the only degree which can be registered, which makes for simplicity and uniformity The close association of university and hospital has been encouraged, and in all four universities at least one hospital is to be found in the university grounds or just beside them Hospital are chosen by students largely on a sectarian basis, and as there is no overcrowding of the courses there are no disappointments Association with the university i close throughout training, and hospital loyalties are thus subject to the more unifying influence of loyalty to a university

Final examinations correspond to the university examinations here The three final subjects, medicine surgery, and obstetrics and gynæcology, must be passed i one sitting, however, a "sitting" includes a supplementary examination, which can be taken in one subject provided the candidate has been successful in the othe two The varied clinical material available give scope for sound practical training, which is continued in the hospital appoi the most successful of its students to fill its resident posts, the appointments are for a year and during this time four months are spent on medicine four months on surgery, and four months on casualty, or some specialty like anæsthesia All men fortunate enough to get a hospital appointment are thus given a wide experience without the necessity for spending too much time at it, or the recurrent bother of searching for a new job every six months At the end of the year registrars are chosen from the residents for a further year and the unsuccessful may pass on to appointments at special hospitals, such as those for women and children

The distances between towns in Australia made it imperative, formerly, that every man should have a reasonable training in operative surgery This was certainly so before 1930, when a house-surgeon was expected to do operations a registrar would be grateful for now Distance however is being annihilated and so the necessity for such a high general standard is diminishing A more important influence has been the rise of the Royal College of Surgeons of Australasia The last war brought many Australian doctors to France and on demobilisation many of them stayed on in England and took the F R C S If this led to a rather narrow prejudice against the Edinburgh Fellowship, it also stimulated those who returned to improve surgical training and status in Australasia This has meant the limitation of the training of the many in order that the few might be better trained, and was met with some criticism at first The relationship to medical education of the College of Surgeons, and of the newly founded College of Medicine, is now settling to that of the English model This trend brings the deeper aims of the profession in Australia still more in line with those of the country from which it sprung, and guarantees that the standards of the past will be steadily raised Australian medical education can well bear comparison with the best available elsewhere, as the increasing number of her notable medical men bears witness

NEW ZEALAND

New Zealand has one medical school at the University of Otago in Dunedin The yearly admission of students fluctuates between 40 and 100 Teaching and hospital work are carried on for three terms in every year, a term lasting 12–13 weeks, and professional examinations conform roughly to the pattern of those in the Scottish schools, from which the New Zealand tradition derives The first year is spent on physics chemistry and biology, the second and third years on anatomy and physiology Pathology, bacteriology, and materia medica are studied in the fourth year, at the end of which there is a professional examination in those subjects At the same time lectures in medicine and surgery are given, and the student works in the wards of the Dunedin Hospital In the fifth year he continues his course in medicine and has classes and clinical work in obstetrics and gynæcology and in the usual special subjects, as well as short courses preparing him for part I of the final examination at the end of the year this consists of public health and medical jurisprudence together with an examination in applied anatomy and applied physiology That concludes the formal part of the student's training In the sixth or final year, the class is divided into four groups, one of which works in each of the country's four large general hospitals (Auckland, Wellington, Christchurch and Dunedin) There the student makes a complete round of the wards and departments, medical, surgical and special, spending about six weeks in each, he studies the patients, assists the house-physicians and house-surgeons in minor procedures and receives clinical teaching from the members of the honorary staff The four hospitals contain over 2000 beds among them At the end of that clinical year the student returns to Dunedin for part II of his final examination (medicine surgery, obstetrics and gynæcology), the passing of which gives him the M B, Ch B degree of the University of New Zealand There is little organised postgraduate teaching, but before the war 30-50% of New Zealand students came to England or Scotland within a year or two of graduation for postgraduate experience and higher qualifications, and a smaller number were beginning to seek the same advantages in Australia

MEDICAL EDUCATION IN THE UNITED STATES

Medical students beginning anatomy and physiology in American schools must have done a minimum of two years' university work which includes prescribed courses in physics chemistry and biology Some medical schools require three years' work and some a baccalaureate degree, and in practice nearly all students taking up medicine are university graduates who have been four years at college, have taken a degree in the premedical sciences and have reached the age of twenty-two They study for a further four years, beginning with an intensive course in anatomy, physiology, pharmacology, pathology bacteriology and biochemistry, lasting through the first two years Though they do not ordinarily start clinical work until their second year in some schools they attend clinical demonstrations given by the most able of their teachers during the first year Set lectures become fewer as they go on At Harvard during their early years no official lecture courses may be fixed for Tuesday, Thursday and Saturday afternoons, though lectures at which attendance is optional and no credit given may be scheduled on those days About 30% of students use the free afternoons for research, their professors advise and encourage them, but the work done is their own affair In the third year of training there is only one lecture a day—often at 8 30 in the morning—and in the fourth year none Clinical classes in small groups are common however, and students and teachers often meet for informal discussion in the evening, learning at such gatherings to know each other well Few fail to do a year or two as interns after qualifying and those who intend to specialise subsequently take resident posts or appointments as registrars, just as they would in England

Graduation from medical school does not give the right to practise The graduate must also pass the state examinations to those states in which he wishes to work or a national examination which qualifies him to practise in any state There is a growing tendency for all students to take the national examination About five years ago examining boards to certify qualification in the various specialties were organised within the profession itself these boards have gained strength and are now able to insist on an appropriate standard of experience and training among examination candidates who intend to specialise There are 77 medical schools in the United States and all except three are recognised as reaching class A This high standard has been achieved in the last generation the Carnegie Foundation drew attention to defects in the medical schools at the beginning of this century and the American Medical Association undertook the task of raising the standard by establishing a system of inspection and control through their Council on Medical Education

Teaching of Preventive Medicine—About a quarter of the schools have a full-time department of preventive medicine and the great majority give organised instruction Where independent departments do not exist this is usually done in connexion with the department of bacteriology, often termed the department of bacteriology and preventive medicine In a number of schools this subject is taught throughout the four years of medical training The view is taken that every doctor must practise preventive medicine, and that those who wish to specialise in it will go into the public health service The whole medical course is built on the study of the three directions in which disease can act, on the patient on the patient's family and on the society in which the patient lives Thus the problem of disease is treated as a group problem Newcomers to the medical school at Harvard are taken on their first day to the Peter Bent Brigham Hospital where they are actually shown a patient—a revolutionary step on the first day of medical training The professor explains the case as he might explain it to intelligent laymen, and having discussed the disease, shows how it has affected the patient his family and the community Thus from their first lecture students grasp the principle that medicine must be approached from these three aspects, and their subsequent education insists on that principle again and again In their fourth year of training, when they are responsible for cases of their own, they are expected to go to the patient's home, to the office or factory where he works

Grand Tour

MEDICAL EDUCATION IN THE DOMINIONS

SOUTH AFRICA

Fully trained graduates of medicine first emerged from the Universities of Cape Town and Johannesburg little more than twenty years ago They showed a high standard of training, served the people of South Africa with enthusiasm and keenness, and are now in many instances holding posts of distinction in England and other countries Thus it proved that a long tradition was not essential to a medical school a new school even had advantages The men who shaped its course came from different schools, and different lands with varying ideas and practice, they were in a position to choose the best and avoid the mistakes of others

The South African medical degree can only be taken at a university—there are no colleges It takes six years, half of which are spent in the wards The student completes his anatomy and physiology by the end of his second year, and though the time spent on anatomy is a little short compared with the time the older surgeons spent on it, it is a sound full course, and extended in the third year by the study of embryology and anthropology During his courses in bacteriology, pathology and pharmacology the student is not able to undertake any serious study of clinical cases lectures and laboratory work make too many demands on his time , but since he is by now hankering for "real doctoring," it might be an advantage if he had the opportunity of attending demonstrations on well-known diseases during this period of training

In the wards the South African student has the benefit of more or less individual coaching in clinical material from junior consultants appointed as registrars Thus his methods of physical examination can be checked frequent discussions preserve him from the tendency to diagnose the occasional rather than the common, and he can be taught the technique of minor operations The registrars are also stimulated by constant teaching to study medical literature and to be precise in examination and diagnosis The student spends a whole year on surgery, followed by a whole year on medicine , in his final year he does both This enables him to attend a full and systematic course of lectures, and to concentrate on reading the textbooks of one subject at a time , it does perhaps lead him to separate medicine and surgery into watertight compartments however Yet the abundance of clinical material in the exceptionally large hospitals attached to the South African universities does much to restore the balance and to give the student the chance to see medicine as a whole

In both universities the system of co-education works handsomely, despite the prejudice against it in some of the London medical schools All South African hospitals provide ample accommodation for women doctors and students They have also recognised the importance of providing good quarters for students In England and elsewhere students often have to live in grimy squalid lodgings near the hospital, which is often situated in a slum area , neither the company nor the atmosphere is good for their health In South Africa large hostels have been built, and these are supervised by the professorial staffs It is recognised that the doctor plays an important rôle in educating the public, and his own education must therefore be a generous one To live among different groups of men, to see, hear and discuss their views is the best way to acquire a broad view of life It might be a good plan to arrange short vacation visits for students from one university to the other, so that they could gain new friends and encounter new teachers and fresh ideas

The South African Government is alive to the importance of its public health services Large tuberculosis hospitals are being established and the problem of venereal disease among the natives is being tackled The white population of South Africa is a limited one and the government has therefore realised the importance of training, for the coloured and the native populations, their own doctors, nurses, midwives and orderl Special hospitals have been set aside for this purp There will be much work for the doctor in the com years The Workmen's Compensation Act and increased wage-earning capacity of coloured work brings them within the scope of private and speciali medical practice The field of specialist practice protected by a committee which allows no-one to pract as a specialist unless he has been approved Po graduate educational demands are already being m and before the war there were regular refresher cour at both universities for medical officers practising in t country districts It is perhaps not too much to hope the whole-time professorial units, envisaged by Lo Nuffield, in which the professor and his assistants c devote their time to the students We may look, to for the interchange of registrars and lecturers betwe countries, which had been begun before the war betwe England, America and Canada Now is the time dream and plan for such things

AUSTRALIA

When this war broke out, a balance between th supply and demand had just been reached amon Australia's doctors after the disturbances of the last wa The present crisis will hardly affect medical educatio in Australia as much as the last one, and any chang are likely to be gradual, conforming to those whic have proved successful elsewhere Medical educatio is in the hands of young and progressive men ther and of recent years minor alterations to the curric ulum have betokened dissatisfaction with presen methods The New Zealand experiment, if successful will not be without influence while any changes mad in England are bound to have their reflection i Australia

Australians have been described as half-way betwee Americans and Englishmen, and a superficial observe might make the same generalisation about their medic faculty Closer examination shows that resemblance t the American schools is skin deep, and comes from th organisation of a university and medical faculty side b side in the large cities The design of hospitals, anatom schools, and affiliated institutions—unhampered as the are by any restrictions of space or need to conform to existing buildings—does remind one of America on smaller scale The medical needs of the population o 7½ millions are served by four medical schools in th cities of Sydney, Melbourne, Adelaide and Brisban the last being the most recently established Premedic subjects may be taken in the universities of Hobart an Perth, the second-year course being continued in one the larger universities The subjects of the cour correspond in all essentials with the English curriculu Second and third years are spent entirely at the universi in the study of anatomy, physiology, bacteriology a biochemistry Clinical training begins in the four year, with the appropriate resident periods for casual dressers and midwifery students Association with t university is maintained, during these years, by t central teaching of pathology public health, surgic anatomy, materia medica, and kindred subjects Exa nations being under the control of the university in ea city, only one qualification—M B , B S —can be obtaine it is also the only degree which can be registered, wh makes for simplicity and uniformity The close associ tion of university and hospital has been encouraged, a in all four universities at least one hospital is to be fou in the university grounds or just beside them Hospita are chosen by students largely on a sectarian basis, a as there is no overcrowding of the courses there are disappointments Association with the university close throughout training, and hospital loyalties a thus subject to the more unifying influence of loyal to a university

Final examinations correspond to the universi examinations here The three final subjects, medici surgery, and obstetrics and gynæcology, must be passed one sitting , however, a " sitting " includes a suppl mentary examination, which can be taken in one subje provided the candidate has been successful in the oth two The varied clinical material available giv scope for sound practical training, which is continu in the hospital appointments Each hospital takes the most successful of its students to fill its resident posts the appointments are for a year and during this time four months are spent on medicine four months on surgery and four months on casualty or some specialty like anæsthesia All men fortunate enough to get a hospital appointment are thus given a wide experience without the necessity for spending too much time at it, or the recurrent bother of searching for a new job every six months At the end of the year registrars are chosen from the residents for a further year and the unsuccessful may pass on to appointments at special hospitals, such as those for women and children

AUSTRALIA

When this war broke out, a balance between the supply and demand had just been reached among Australia's doctors after the disturbances of the last war The present crisis will hardly affect medical education in Australia as much as the last one, and any changes are likely to be gradual, conforming to those which have proved successful elsewhere Medical education is in the hands of young and progressive men there, and of recent years minor alterations to the curriculum have betokened dissatisfaction with present methods The New Zealand experiment, if successful, will not be without influence, while any changes made in England are bound to have their reflection in Australia

Australians have been described as half-way between Americans and Englishmen, and a superficial observer might make the same generalisation about their medical faculty Closer examination shows that resemblance to the American schools is skin deep, and comes from the organisation of a university and medical faculty side by side in the large cities The design of hospitals, anatomy schools, and affiliated institutions—unhampered as they are by any restrictions of space or need to conform to existing buildings—does remind one of America on a smaller scale The medical needs of the population of 7½ millions are served by four medical schools in the cities of Sydney, Melbourne, Adelaide and Brisbane, the last being the most recently established Premedical subjects may be taken in the universities of Hobart and Perth, the second-year course being continued in one of the larger universities The subjects of the course correspond in all essentials with the English curriculum Second and third years are spent entirely at the university in the study of anatomy, physiology, bacteriology and biochemistry Clinical training begins in the fourth year, with the appropriate resident periods for casualty dressers and midwifery students Association with the university is maintained, during these years, by the central teaching of pathology, public health, surgical anatomy, materia medica and kindred subjects Examinations being under the control of the university in each city, only one qualification—M B, B S—can be obtained, it is also the only degree which can be registered, which makes for simplicity and uniformity The close association of university and hospital has been encouraged, and in all four universities at least one hospital is to be found in the university grounds or just beside them Hospitals are chosen by students largely on a sectarian basis, and as there is no overcrowding of the courses there are no disappointments Association with the university is close throughout training, and hospital loyalties are thus subject to the more unifying influence of loyalty to a university

Final examinations correspond to the university examinations here The three final subjects, medicine, surgery, and obstetrics and gynæcology, must be passed in one sitting, however, a "sitting" includes a supplementary examination, which can be taken in one subject provided the candidate has been successful in the other two The varied clinical material available gives scope for sound practical training, which is continued in the hospital appointments Each hospital takes on

The intensive clinical teaching was found to be very uccessful and the general tendency was to increase is side of a student's medical training and to attach less nd less importance to the systematic lectures which gured so prominently in the education of our predecessors A certain amount of purely theoretical instruction was given either by professors or by "auxiliary professors," as they were called, but a student received he greater part of his teaching at the bedside Having ompleted their medical course many would continue working in one of the hospital departments (usually hose in which they had spent most time as residents) until hey obtained hospital appointments, or started in general practice This led in the larger hospitals to the organisation of a regular postgraduate medical course lasting for two years Students were thus able at little expense to continue their study of general medicine or take up a special subject in which they were interested At the end of this postgraduate course students were well qualified to take up a regular appointment in a hospital, and such appointments were given in preference to students who had taken the course

The general tendency of medical training in my country was thus to concentrate on a practical clinical education as soon as a sufficient groundwork of knowledge had been acquired by theoretical instruction There was also repeated selection of the best students throughout the whole course First students were picked out to be junior residents, two years later another selection was made for the senior residentships, and again at the end of the course the best students were chosen for postgraduate work The pick of these again were selected to fill hospital posts, in which they could continue to work at the subject of their choice This system of repeated selection was in process of organisation, and in my opinion promised to lead to good results, it kept graduates in close touch with an individual teacher and led to the growth of regular schools of medical thought, between which there sprang up a healthy rivalry which served as a stimulus and raised the standard of medical efficiency all round The principle of selection went still farther Grants were available from both public and private sources, which enabled postgraduates to study abroad for one or two years Many beneficiaries went to Austria, Germany, France and Italy while a few went to the United States of America I do not know of any coming to Great Britain and believe this to be due to a lack of contact between the medical professions of the two countries To our doctors it appeared that the golden age of British medicine was represented by Lister, Lane, Moynihan Starling Robert Jones and others of their day, and that it was over, while few British medical men of today have knowledge of the important work done by Ramon y Cajal Turro, Pi i Sunyer, Corachan, Cardenal, Del Rio Hortega Puig Sureda, and others I sincerely hope that this unfortunate lack of contact will come to an end after the war for the mutual benefit of the younger members of the medical profession in both countries

CZECHOSLOVAKIA

There is a medical faculty in each of the four Czecho- vakian universities—the two famous ones, Czech and erman at Prague, and in the Czech university at Brno d the Slovakian at Bratislava At the founding of the echoslovakian Republic no substantial change was ade in medical education, the regulations laid down by e Austrian government remaining in force Under ese regulations students passing the final examination the *gymnasium or realgymnasium*—which correspond the English grammar school—were at liberty to enter y of the university faculties The universities were der government control but had some degree of tonomy, their staffs were employed and paid by the ate Students' fees for medical studies were very low, mounting to about £5 a year apart from their examination fees which were about £7 in all Those who lacked fficient means—and most of them did—were exempted om paying any fees at all

The medical course was divided into preclinical and linical periods each lasting five terms, there were two rms yearly, and about ten weeks vacation Preclinical students attended lectures and practical classes n biology, physics, chemistry, anatomy histology and physiology Lectures were given by the director of the institute and by assistant professors holding special qualifications in their own subjects The director gave a systematic course of lectures—at which attendance was compulsory—covering the whole syllabus, 1–1½ hours daily being devoted to each subject The course in each subject lasted 2–4 terms, depending on its importance and complexity Lectures given by the other professors were designed to interest students in special problems and attendance was optional Altogether about 5 hours daily was spent at lectures No steps were taken to enforce attendance and students were "signed up" at the end of the course almost automatically nevertheless attendances were fairly regular There were about 350–500 premedical students at Prague so that there was little personal contact between them and their teachers An examination in biology and physics was taken at the end of the first year, and in the remaining preclinical subjects at the end of the second year These examinations were purely oral, the instructor giving the main course of lectures being the examiner The examinations were held in public and the fellow students of the candidate were admitted, a representative of the government who had the virtual right to interfere was also present and the dean of the faculty usually attended A student who failed could repeat the examination in 2–6 months' time but if he failed three times he was only allowed to continue the study of medicine by special permission of the government

During the clinical period of training lectures predominated The central hospital was at the disposal of the university, each clinical department having its own director and staff and its own lecture theatre Lectures were given daily by the director of the department as a systematic course covering his subject with demonstrations of appropriate cases, students would often be asked to take part in these demonstrations Lectures on medicine and surgery extended over 4 terms, those on other subjects over 2–3 terms Optional lectures were given on methods of examination and on clinical pathology Students lived in hospital for a week during their obstetric course There was no compulsory clerking or dressing in the wards, but students had an opportunity to act as clerks at the medical clinics, they were generally not admitted to surgical clinics A short course in vaccination was compulsory The final examination was in two parts, each comprising six subjects. part I in general and experimental pathology, pharmacology, medicine neurology and psychiatry, and children's diseases, part II in hygiene and bacteriology, forensic medicine ophthalmology, dermatology, gynæcology and obstetrics and surgery Most students attended special classes to prepare them for the examinations, these were conducted by the assistants with the consent of the directors of the various departments, and since they were really private classes a fee of 1–2 guineas was charged The clinical parts of the final examination included examination and discussion of a case, and a viva voce examination The successful candidate received the degree of doctor of medicine but since the government recognised the lack of practical experience in the course a year's work at hospital was compulsory before the newly qualified man could practise

RUSSIA

A correspondent writes I worked in Russia in 1934 but life changes rather quickly in the U S S R While I was there the medical curriculum was in a state of flux Just before a totally new curriculum—in which examinations and lectures found a very small place—had failed to work Its basic idea was that a small group of students working together throughout the whole of the medical course were taught together as a unit They even used to pass their examinations as a unit Theoretical lectures dropped out and their place was taken by discussion and practical work This was a natural outcome of the thesis that students must not be divorced from their future jobs thus engineering students worked part time in factories and were in fact often enrolled from factory workers Night courses were common But this so called group system proved less easy of application to the medical course and was finally abandoned although I believe it may still return in some modified form Whether its abandonment was mainly and if need be to the public-health department asking themselves "What has this illness done to this man for whom I am responsible ?"

MEDICAL EDUCATION ON THE CONTINENT

THE CURRICULUM IN FRANCE

To register as a medical student in France, it is necessary to produce a baccalauréat diploma, a birth certificate and a certificate of recent vaccination There is no alternative to the baccalaureat which consists of two parts The first part may not be taken before the age of sixteen and a year must elapse before the second examination The first examination consists of ordinary school subjects the second of higher mathematics and science, psychology and philosophy After passing this the student has the choice of some twenty universities in which to take his premedical course or "P C N" (physics, chemistry and natural science) This course is identical with that taken by science students and lasts one year

The medical course takes a further six years after the P C N Most medical students elect to go to Paris for their training, with the result that, before the war the average number of students in each year at the University of Paris was over a thousand—as there is only one school of medicine in the university, the classes are very large In the first year of medicine the student attends hospital practice (ward work and lectures) each morning from 9 to 12 A six months' course in surgery is followed by a six months' course in medicine In the afternoons practical classes in anatomy and histology are held from 1 to 4 P M in the medical school, while lectures in these subjects are given each evening from 5 to 7 P M In the second year he continues his hospital practice in the mornings, but his afternoon classes and evening lectures are in physiology and parasitology In the third year he attends a children's hospital for six months and then does a further six months of medicine or surgery Afternoon classes and lectures in pathology, operative surgery and obstetrics are held at the same times In the fourth year he takes gynæcology and obstetrics for six months and neurology for the rest of the year Each student is required to manage 25 accouchements, all of which are carried out in hospital Afternoon classes and lectures are in bacteriology, pharmacology and materia medica He attends the morgue for post-mortems Fifth-year hospital practice consists of diseases of the skin, ophthalmology and psychiatry The classes and lectures are in hygiene, medical jurisprudence and therapeutics The sixth year is devoted entirely to clinical medicine, surgery and midwifery with lectures in these subjects at the medical school

At the end of each year written oral and practical examinations are held, both at hospital and at the medical school, in the subjects of the year's curriculum The student must obtain pass marks in these examinations before proceeding to the next year's course They correspond to the examinations of the English curriculum To pass in clinical medicine surgery and midwifery at the end of the sixth year does not confer the right to practise A thesis must be presented to the university council before the medical diploma is granted This diploma of Docteur en Medecine is issued by the state and not by the university Under certain conditions foreign students are permitted to take the full medical course without first passing the baccalaureat At the completion of the course the student receives a university diploma which does not however, carry with it the right of registration or practice

Specialisation —Diplomas are granted in special subjects such as hygiene, ophthalmology and radiology but there are no "higher examinations" in France Their place is taken, in Paris, by a series of competitive examinations called "Concours des Hôpitaux" At any time after the end of the second year of medicine the student is entitled to sit the examination of "Externat" The subjects are anatomy, medicine and surgery and the examination is held once a year There are some 300 posts to be filled every year and they roughly correspond to the junior resident and outpatient posts in a London hospital The number of candidates is about 1500 The appointment is for six years and replaces the hospital training of the ordinary student

At any time after the end of two years as an "externe the student may sit the "Internat" examination This is a more difficult examination in the same subjects and is also held once a year There are 80 posts corresponding to the resident posts in a London hospital, to be filled every year from about 400 candidates The period of "internat" appointment is limited to four years An interne intending to specialise may after obtaining his degree, apply for the position of "chef de clinique" (corresponding to registrar) which is decided by competitive examination When a vacancy occurs on the staff of a hospital the appointment is again decided by *competitive examination from among graduates* who have held the post of chef de clinique University professors are selected from "agreges"—that is, those who have passed the competitive examination known as "Agrégation" The number of agreges for each chair is limited to five or six

SPAIN

Dr Josef Trueta writes Until the last few years Spain had two distinct state organisations both in the political and in the educational sphere—that of Catalonia and that of the rest of Spain When Catalonia regained its educational autonomy the Spanish educational system was well developed, and the medical organisation of Catalonia was based on the best elements in the Spanish system Further improvements were in progress when the autonomous University of Barcelona was suppressed I shall confine myself to a brief account of the medical training in Catalonia as it was when I took part in it, since this comprised the best features of the Spanish system After six years of general education culminating in an examination comparable to the English school certificate, a student who wished to take up medicine devoted a year to the study of chemistry, physics botany, zoology and mineralogy After passing an examination in these subjects he was allowed to enter the medical school, where he spent six years before qualifying The first two years were devoted to the basic subjects of medicine—anatomy, physiology, biochemistry and histology—the third year to general pathology and therapeutics and the final three years to clinical medicine At the end of the six years course the student's name was inscribed in the medical register and he was allowed to practise as a licentiate in medicine and surgery He could also submit a medical thesis to a qualified board of examiners, which would be carefully scrutinised and if approved, would secure him a doctor's degree

Such were the general lines of a medical student's educational career While receiving his scientific training he would also be studying medicine from the practical and clinical point of view In the first two years he divided his time between attendance at lectures and practical work in the anatomy department and laboratories At the end of this period a selection of the students was made, and the best (often a quarter of the total) were taken into the hospital as "junior residents," where for the next two years, in addition to continuing their normal studies they helped the "senior residents" and doctors in dealing with patients and learned the elements of clinical work—how to give injections, take temperatures, write up charts and apply bandage After two years as juniors the best students became "senior residents" helping in the treatment of patient, writing clinical histories, examining patients with the junior medical officers, making plasters, learning the technique of anæsthesia and later giving anæsthetics under the supervision of a doctor After six months in one particular branch of work a senior resident could transfer to another but he could also continue in the same branch if he wished Those students who had not been selected as residents also assisted in the various hospital departments, as compared with the residents they received a more theoretical and a less practical education Students were instructed by the professors who held chairs at the hospitals The large size of the teaching hospitals in Barcelona greatly facilitated teaching, the General Hospital of Catalonia had nine professors of various clinical subjects and students could complete the whole of the second part of their medical course in this one hospital This was important in a large city where much time might have been wasted in travelling from one teaching centre to another lso attend courses in dermatology, eye conditions, venereal diseases, pharmacology and hygiene. At the nd of three years they take a written examination and n oral in which they are questioned on their findings n examining a patient. Part III of the course takes another year during which students are instructed in gynæcology, obstetrics, psychiatry, ear, nose and throat conditions, children's diseases and forensic medicine. During their obstetric training students live in hospital in small groups and attend the maternity cases admitted. The final examinations are held at the end of the year and the newly qualified doctor receives the "Licentia practicandi." Most of them choose to work for some years as assistants to general practitioners before going into practice themselves and some have an opportunity to continue their education with a view to specialising.

POLAND

A member of the Polish School of Medicine, Edinburgh, writes: Before the war five universities with full medical faculties were functioning in Poland. Warsaw was the largest, serving the central and eastern part of the country; Krakow served the south-west, Lwow the south, Poznan the west, and Wilno the north. The universities provided complete medical training, theoretical, practical and clinical.

The medical course lasted sixteen terms of ten weeks each. There were many applicants, but since only about 200 could be admitted yearly to each university (owing to limitations of clinical material and laboratory accommodation) candidates had to sit a preliminary examination. This consisted of written papers in biology and general subjects.

At the university the work started at 8 A.M. and lasted till 6 P.M. or later, with two hours interval for lunch between 1 and 3 P.M. In the first year the chief subjects were anatomy, histology and embryology, chemistry and physics; in the second year anatomy, histology and embryology, physiology, biochemistry, and biology. In the mornings students attended lectures, and in the afternoons (3 to 6 P.M.) did practical work. In the third year they took an introductory course to clinical medicine, to familiarise them with methods of examination, and courses in bacteriology, pathology, pharmacology and morbid anatomy. Serious clinical teaching began in the fourth year, the last seven terms being almost entirely devoted to it except for courses in morbid anatomy, forensic medicine and hygiene. During their fourth and fifth years students passed their afternoons in the wards (about four hours weekly in major and two hours weekly in minor clinics) examining cases. They also had patients allotted to them, and took the case-history; their notes were corrected and criticised by the assistant medical officers. They were on duty for several days and nights in the year, living in the clinic to gain midwifery experience. They worked in the wards under the supervision of senior and junior assistants, who helped them in examination of the patients and taught them simple laboratory tests, such as the examination of urine and stools, blood-counts, analysis of gastric juice, and of pathological fluids. They also had the opportunity to give injections, dress wounds, and help in minor operations. The lectures, generally accompanied by demonstration of cases, were given by professors or docents (associated professors). Purely theoretical lectures during the clinical years were few. The last term was spent in the outpatient department.

In the last few years before the war a new scheme of clinical teaching was under consideration, Warsaw University being the first to introduce and test it. The main plan was to provide students in the final two years with as much clinical practice as possible; from 8 A.M. till 11 A.M. was therefore reserved for hospital work (15 hours a week). Students were divided into groups, each group spending two weeks three times a year in the medical or surgical wards. Thus every student had twelve weeks experience in those wards during the fourth and fifth years, the rest of his time (eighteen weeks) being divided among minor clinics. In the wards he was attached to the senior assistant and took part in the routine work; only two or three students would be under the care of an assistant at a time. From 11 A.M. till 1 P.M. and from 3 P.M. to 6 P.M., or even later, students attended clinical lectures.

Students had to sit one or two class examinations every year. At the end of the first year they had to pass the first professional examinations, in chemistry and physics, before they were admitted to the second year. At the end of the second year they had to pass in anatomy, histology and embryology, physiology, biochemistry, and biology. They were allowed, if they wished, to sit the professional examination in bacteriology, pharmacology and pathology at any time after the end of the third year. After the sixteenth term the examination subjects were divided into five groups:—

1. Bacteriology, pharmacology, and pathology for those who had not already passed them;
2. Morbid anatomy and pathology;
3. Medicine, skin and venereal diseases, neurology and psychiatry, and children's diseases;
4. Surgery, gynæcology and midwifery, eye diseases, laryngology, and one of the following—stomatology, roentgenology, or orthopædics;
5. Forensic medicine and hygiene.

Each subject could be taken only twice. If he failed in the first or second professional examination the student had to repeat the whole year. If he failed twice in the finals he could only sit a third time by permission of the Ministry of National Education; if he failed again his career as a medical student ended. When qualified he had to work for a year in a hospital recognised by the State as a teaching hospital for newly qualified doctors, before being allowed to practise. The period had to be spent in various wards, the aim being to produce a general practitioner. After this experience he could go into practice or specialise at some hospital or clinic chosen by himself.

The university unions were partly social but had two other aims: to publish lecture notes and medical books, and to offer financial aid to poorer members. Medical students formed circles which had their own hostels and unions, built and maintained from their own funds, with the help of the medical profession and the State. They also organised students' sports.

Life throbbed vigorously in the medical faculties, and every year saw an advance. After the war of 1914–18 we started to build up most of our universities from scratch. We advanced quickly, organising laboratories and clinics, reinforcing and educating our teaching staffs, and carrying out research on a large scale and publishing the results in Poland and abroad. The ardour of the workers, who though often earning only just enough to live on were spending almost their whole time in the laboratories and clinics, produced a magnificent result. The number of publications, their themes, their scope of interest, and the repercussions which they caused in our own country and abroad, are the proofs that we marched with other civilised nations. The war in a few weeks' time entirely destroyed all this, for which we had struggled. But the war has not killed our own medical studies. Our Polish school has taken firm root in Edinburgh, and is to have access to the new Paderewski Hospital for Polish civilians which is shortly to be opened there. Polish medical thought will revive and develop as soon as liberty once again lights the sky above our beloved and now martyred country.

GERMANY THEN AND NOW

The medieval tradition of the wandering scholars has always lingered in the universities of Germany. Before the days of Nazi rule a medical student would often begin his premedical studies at a small university such as Heidelberg, Jena or Wurzburg, leaving at the end of a year to go to Kiel, perhaps, for six months, thence back to Heidelberg for a year, and then to one of the larger universities—Munich or Breslau—for clinical experience. Migration of students from one university to another was facilitated by a standard curriculum throughout Germany, and by the fact that there was only one qualifying examination—that conducted by the State. Just after the last war the course took five years, but the student did not receive his degree until he had completed a year's internship after passing his final examination. Later the course was lengthened to five and a half years, the additional year of internship bringing it up to six and a half. The subjects studied are the same as those in English schools: biology, physics and chemistry for a due to the lack of teachers, equipment, or sufficient premedical education of the students is difficult to say The scheme was dropped, however, as was a scheme of very early specialisation in the student's course At that time a more typical European five-year course was instituted, but was intended to be only transitory until something really good and adaptable to Russian conditions could be devised I had to show all my " duly performed " certificates from my university to Kaminsky, then medical chief of the R S F S R He felt certain that he could substantially improve on our curriculum , whether he did I don't know—I rather think he might have done The students were all keen, in a way that was different from ours They were workers on a salary, a system which makes it easier to combine them as a part of a university or hospital The ratio of women students at that time had grown to at least 80% , but later, with the increase of wages of doctors, and the completion of industrial plans the profession again became more attractive to men

Much emphasis was laid on postgraduate work I worked in a clinic of which the objects were threefold treatment, research and postgraduate teaching Doctors there had an opportunity to specialise and to prepare for teaching positions in the provinces All doctors were on salary and there was hardly any distinction between doctors permanently employed at the clinic, those staying for fairly long periods and those there only for a short time The working day at that time was from 9 to 1 or 2 , afternoon and night duty was divided between the doctors—there were no residents All permanent staff or those engaged for a long time were expected to join in research and spend the rest of the time reading Enthusiasm for the work was extremely high, and the money motive seemed to be non-existent Languages and journalistic ability were at a premium at that time, and as many of the doctors knew foreign languages they could have doubled or trebled their salaries by doing translations I could not find one who was willing to give up his time to this type of remunerative work

The clinic was for gastro-intestinal cases It was situated in the largest Moscow hospital and disposed of 200 beds It had its own X-ray department, physiotherapy department, research laboratories and theatre for animal experiment There was one doctor to every 5–10 beds A professor or his assistant gave lectures every day, alternating clinical with outpatient lectures Foreign books and papers quoted were mainly German or American—rarely English , but this may have been because there was little to quote from on this subject

Nursing facilities at the clinic were extremely poor and drugs were difficult to procure For pure research work and specialisation it was unbelievably good for all-round postgraduate work insufficient This, however, did not come within its scope though it would have been extremely valuable to some of the men if it had offered a comprehensive postgraduate course

ITALY

About five years ago medical studies in Italy were sweepingly reformed The aims were to raise the standard of newly qualified men and to reduce the numbers entering the profession An attempt was also made to bring students into contact with patients from their earliest years of training Medical training lasts six years and students are required to take 26 examinations arranged in 3 groups The course is divided into three periods of two years each, and a group of examinations is taken at the end of each period All examinations are oral and practical without written papers, a system which has the drawback that it may be difficult for an examiner to discover what a shy candidate really knows Admission to the second and third parts of the course is refused unless the student has passed all the preceding examinations This makes it possible to eliminate candidates who are not up to the required standard The student is admitted to the wards during his third and fourth years of training and begins the study of general medicine and surgery During these years he is given no responsible tasks in the hospital, but the honorary physicians and the medical officers in charge of the wards give him all possible help in his first contact with patients and hospital routine

On admission to the third part of the course, during his fifth and sixth years of training, the student receives systematic instruction in medicine, surgery, midwifery and gynæcology, and the specialties He spends at least a month in the wards of each special department and a minimum of 60 days each on the study of general medicine, surgery and midwifery He begins to take responsibility for patients, under the supervision of the ward medical officer On passing his final examinations and gaining his degree the student must submit an original paper to a committee composed of twelve members of the university , three members of the committee who are acquainted with the content of the paper discuss it The choice of subject is left to the student, who works on it during his training The papers seldom achieve publication, but on the whole they contain useful material and give the student a chance to test his capacity as a research worker and to become familiar with laboratory technique His medical degree does not entitle him to practise immediately He must study medicine, surgery and midwifery for another six months before he is admitted to the State examination, which requires a high standard of knowledge and entails three oral and practical examinations covering the whole field of medicine When he has passed this, he is registered as a general practitioner

The student is somewhat hard-pressed with work throughout his course, but the hospitals cooperate closely with the universities and lecture hours are so arranged that they do not conflict with work in the wards The new system has the advantage of bringing students into daily contact with patients over a period of nearly five years

NORWAY

The medical profession in Norway is overcrowded, entrants far exceeding the demand At the University of Oslo, the only university in the country, students choose medicine as a profession more commonly than any other The curriculum was laid down at a time when the numbers of entrants were proportionate to the needs of the country, and it can therefore only be adapted to meet the present situation with difficulty Thus the original length of training was 7 years, but in the last decade overcrowding has become so serious that the student cannot reckon on completing his course in less than 9 years he has to wait his turn Places in the university and teaching hospitals are limited and only about a hundred students can be admitted yearly

Students begin work on biology before leaving school Medical training is divided into three parts Part I begins with a year's study of organic and inorganic chemistry and physics, terminating in an examination Students then proceed to biology and embryology, anatomy and physiology, biochemistry and histology During this period they dissect the body, work at practical physiology and attend lectures from the professors They also meet in discussion groups (colloquia) from which they learn a good deal So far membership of these groups has been voluntary but they are likely to be adopted as part of the training course in future, groups of five being formed under the leadership of a teacher , membership will then become compulsory The standard of the examination at the end of part I is high and 40–45% fail The hospitals in Oslo have room for only 50 students each semester, or half-yearly term Those who are happy enough to get through part I are now ready to begin part II, which is clinical Training is carried on in the hospital wards and by lecture courses Unfortunately students may have to wait 2–3 years between part I and part II, until there are places available in hospital Some fill in the interval by doing practical work in small hospitals in the neighbourhood of their own homes, but not all are fortunate enough to get the chance This interruption of training is often a serious drawback

Part II takes about three years, most of the time being spent in the wards The students are divided into small groups working under the supervision of a professor and his assistants They gain much the same experience as students in England, examining patients, writing up case histories, attending lectures, and working in the laboratories at pathology and bacteriology They are questioned about their cases by the professor before the rest of the class, just as students here are " ragged " They f the times—the perfect setting in fact for a golfing oliday as we used to know it

Many of our patients are not particularly ill but that act does not make them any easier to nurse Some are ery willing to be spoiled and some being human willing nough to grumble It is notorious that officers are far nore difficult to care for than other ranks (not of course ll officers for many of them are eminently reasonable) Ve often wonder how far the hordes of County visitors vho haunt our corridors contribute to the contentment of the hospital We have repeatedly had occasion to uspect that their intromissions were not an unmixed blessing They are willing enough to take an occasional officer patient home to lunch, and doubtless to do him very well bringing to his menu on that occasion grouse and a variety of other things not always obtainable by ordinary mortals It is an easy step from that to commiseration with the hard lot that deprives the poor boys of their sherry and their caviare and an easy step to infer that there must be something wrong with the standards of a hospital that is content with simpler fare When with their units, officers participate in such mess arrangements as they collectively wish to adopt and it is often open to them to supplement their diet from sources not normally available either to the man in the street or to civilian hospitals It is not surprising that they notice the transition that hospitalisation is apt to involve But it is difficult to believe that reasonably adequate plain fare for two weeks or even three, undermines their physique to any appreciable extent or does them any real moral or physical harm Many people doing quite a lot of active work would think they were being very well fed on a regime that brought to them (to take a typical day) at 6 30 A M. a cup of tea ; at 8 30 A M breakfast porridge grilled tomatoes on toast rolls at 11 A M Bovril cocoa or milk , at 1 P M lunch curried mutton, potatoes baked rice peaches and custard biscuits and cheese at 4 P M tea white and brown bread scones butter jam , at 6 45 P M dinner potato soup roasted chicken bread sauce green peas and potatoes steamed pudding and custard, coffee , and at 9 P M Ovaltine, cocoa or milk That does not sound unbearable in the summer of 1941 It is, indeed a question how far it is desirable that the same base hospital should cater for both officers and men except under conditions of real emergency There might well prove to be advantages in segregating officer patients in a hospital of their own under conditions and discipline compatible with their status and enabling them to make such communal arrangements as they please to eke out official rations, in the knowledge that they would then be able to supplement their diet to their hearts' content That might conceivably breed real contentment

* * *

These moral jerks at 7 55 A M still follow the old accustomed lines girding the national spirit for war hardening the erector spinæ of resolve the pectorals of perseverance, and quite right too Perhaps it would never do to be experimental like this —

" I want to talk to you this morning about those much maligned but valuable biological virtues called Jealousy and Envy, which I need hardly remind you are closely related to the perfectly respectable Zeal and Insight t is true that throughout the ages they have been held up to scorn and ridicule but that is because the position of all preachers and other leaders is directly threatened y them You will notice they very rarely attack the ibling their favourite Ambition Yet these are aluable qualities , they tend to haul any man who seeks o get above his fellows back to the common mean hey make him watch his step lest he get too far ahead hey are Nature's thermostat the dictator's bane Hitler, by killing off the people who might be actuated y these useful qualities—a most unnatural crime— as placed Germany in a precarious biological condition, mass of people obedient to the unsafeguarded will or him of one unbalanced man "

I don't think I ever guessed at the mechanism until I aw it in operation in larval form Before the war I went for a number of years to a large mixed boys' camp nd every year the same thing happened The camp tarted off harmoniously, if shyly , under adult direction apparently leaders who are grossly dissimilar in age from he led don't evoke jealously (Pitt and Petain) Then about the third day the camp chief gave his celebrated little talk on ' leadership holding up for the boys' emulation a projection figure of a fearless hard-working, self-sacrificing loyal yet withal modest youth Thereafter the camp got much more interesting for it became not so much a competition in these qualities as a competition in the display of them a very different matter The display of modesty for instance needed great subtlety or possibly a friend who'd act as publicity agent It was from observation at this most amusing camp that I found out several things about envy and jealousy in relation to leadership which are doubly true of adults for these virtues don't really come to their prime till the fourth and fifth decades the leadership age Envy and jealousy are much stronger in the friends and associates of a leader than in strangers to him if one could measure these things up I expect they would be found to increase with the cube of the friendship When they are very strong as among a group of intimates, the leader must be one of them who is well below mediocrity, or he may even have to be chosen from outside the group The mechanism is abolished when self-preservation is in question—envy and jealousy vanish on the threat of real danger Leaders then have the loyalty even of their friends (Chamberlain September 1938 Churchill 1940–?)

ASSOCIATION OF CLINICAL PATHOLOGISTS

ABOUT 60 members and guests attended a meeting on July 19 of the association in the pathological department and St Catherine's College Cambridge

Dr J F GASKELL described 7 cases of fatal acute pancreatitis in Cambridge between 1932 and 1934 The patients were in vigorous health but died within a few hours in several cases shortly after a full meal At necropsy done usually within 24 hours acute hæmorrhagic and even necrotic pancreatitis apparently of antemortem origin was found No association between the cases could be traced and no significant microbes were found A footballer died on the field the suggestion being that the head of the pancreas had been squeezed against the spine by another player s knees

Dr G A HARRISON and Mr L E R PICKEN Ph D , described and demonstrated the preparation of blood-serum for transfusion (*Lancet* 1941 1, 536) Ordinary dry blood bottles were used and about 47% yield of serum was obtained The resultant serum remained clear at room temperature Among 102 transfusions pyrexia with rigor occurred once and without rigor four times—that is, reactions occurred in about 5% On the assumption that the body contains 10 pints of blood and that a hæmorrhage of 6 pints is the largest compatible with survival the maximum amount of serum that could be required even in the worst cases would be 3 pints—i e , half the volume of blood lost (*Ibid* p 685) In most transfusions one bottle of serum had been given Defibrinated blood was also prepared 30 c cm of glass beads shaken in the blood gave good defibrination (*Ibid* p 405) If the blood were not used the serum could be recovered later

Dr A M BARRETT pointed out the importance of details of technique in deciding titre in the Paul-Bunnell test for glandular fever Horse red cells give a somewhat higher titre than sheep cells Of 100 normal human sera none agglutinated sheep cells at 1 80 4 gave titre of 1/80 or slightly higher with horse cells Of 27 cases of glandular fever 17 gave a titre of 1/640 or slightly less with sheep cells 10 had a higher titre With horse cells 11 gave 1/640 or less and 16 showed a higher titre The slight titre in normal sera can be abolished by absorption with Forssman antigen (guineapig kidney) whereas ox cells will absorb the true glandular-fever hæmagglutinin

Dr S C DYKE showed curves of blood-counts during trichiniasis (*Lancet*, July 19 1941 p 69) The rise in the total white cells may not start for about a week , it reaches in the average case about 18 000 at three weeks and drops to 9000 at seven weeks with a temporary secondary rise to 19 000 at about ten weeks This curve runs parallel to the eosinophil curve since it is the eosinophil increase that mainly causes the leucocytosis During the early reduction or absence of eosinophil cells eosinophil granules may be found in the poly-year anatomy, physiology and biochemistry for eighteen months , and then clinical work The early part of the clinical years, however was spent largely in the lecture-rooms The student attended lectures and demonstrations throughout the day in all the subjects of his syllabus and did not "take a case" in the manner of the English ward clerk until he had reached his second or third year of clinical work The effect of this was to give him an exceedingly sound background of theoretical knowledge, which served him well later in life , but it was heavy going His final years were spent in getting practical experience not in one but in several hospitals The final examination was very long, often occupying two months or more, and divided according to subjects into more than twelve sections surgery, medicine, obstetrics, gynæcology, hygiene, pharmacology, surgical anatomy, pathology, ear, nose and throat diseases, ophthalmology, psychiatry, pædiatrics and forensic medicine Hygiene covered a wide variety of subjects, including social and prophylactic medicine, public health, insurance medicine and bacteriology The hygiene course occupied four hours weekly for a year and was followed by a practical course in public health in which house construction sanitation and water-testing were studied and visits were paid to sewage farms, sanitary institutes, water works and public-health departments Thus the student received a much more thorough grounding in the social aspects of medicine than his English contemporary He was also taught pharmacology much more thoroughly lectures on toxicology and the action, chemistry and biological effect of drugs being given throughout the period of clinical teaching , prescribing was taught separately in a short course

Just before the Nazi regime began, the medical curriculum was under discussion and experimental changes were being made in it These reforms placed more emphasis on the practical side of training and less on detailed scientific instruction The balancing of the various specialties roused as much controversy there as here every exponent believed his subject to deserve a prominent place in the final examination With the coming of the Nazis and the preparations for war these academic dissensions were cut short , the government insisted that subjects useful to the military organisation should be given precedence Doctors were to be trained for the army and the air force , and Hitler's hobby, "race biology," ousted a growing interest in prophylactic medicine The emphasis thus swung towards the practical side lectures were replaced by practical classes and students were brought early into contact with patients This was in accordance with the Nazi principle of discouraging too much spontaneous thought and they carried it through with their usual fervour Curiously enough it had the effect of bringing the German curriculum—which had previously been overweighted by science and theory—more into line with the British and French type of education Every medical student was obliged to act as a nurse in hospital for some months before beginning his clinical work—a piece of practical experience which he probably found invaluable

The self-inflicted loss of many Jewish doctors left the state poorly supplied, and it might be supposed that official encouragement would be given to young people to take up medicine No such encouragement seems to have been given, however, but the shortage has been partly met by a law made in February, 1939, legalising quacks and nature healers , indeed, chairs of nature-healing—as well as of race biology—have been established in the universities One keen supporter of this movement, permanent patient of a well-known nature healer of Munich, was that uninvited tourist Hess The Nazis have made another effort to overcome the shortage, and one which inspires even less confidence, by shortening the period of medical training by something like two years We shall have an opportunity to study the result when the war is over

---

MESSRS BRITISH DRUG HOUSES have issued a useful booklet which includes, besides a price list of the B D H standard stains and other materials for microscopical work, detailed accounts of methods of staining, fixing and mounting It also introduces a new histological agent, "Mollifex," for softening tissues embedded in paraffin wax

In England Now

A Running Commentary by Peripatetic Correspondents

I CEASED to be a consulting physician in London, at any rate for the time being in July 1940, and three months later I re-started in the depths of the country where as it happened I knew nobody I called on the doctors who remain and was told that no fortune awaits me , this is probably true, but country work has provided some compensation Here the greater part of my work is done at the patient's home • I hire and a native drives me but even so and with a good map the absence of signposts reduces near-certainty to hopeful probability My wife is able to share the drives, which was seldom convenient at home Care is as necessary as in London on account of the narrow lanes and wandering cattle Pheasants I know, but I wish I knew the names of all the birds I see I have not yet met fox or hare On May 6 at 2 A M during an appalling blitz on the near-by town a nightingale demonstrated its complete indifference I take my London bag but here also the only essential requisites are the ophthalmoscope, litmus, finger-stalls and needles Cisternal puncture, comparatively modern, performed in a farmhouse many hundred years old, intrigued both me and my partner, and afterwards we watched salmon leaping, an experience I had gained previously from photographs alone Old clothes go on for ever and they do not weary if the cut is right The informality of cricket shirts has virtue and for twelve months I have worn neither hat nor cap London conventions have come to seem largely meaningless and when patients come to me they use an expression which I never heard during the 23 years in Harley Street since I was demobilised—"How beautifully you are situated" Other old things besides clothes are proving of unexpected value A large hydrocele turned up to be tapped a few weeks ago, and I was able to lend the doctor from my bag the nest of trocars and cannulas which I had not taken out of my dresser's case since I qualified in 1907 Another day a local doctor after driving me back from a consultation asked me if I would give him a hand with an autopsy at the local mortuary A man had died suddenly at the tea-table The coronary arteries came under suspicion but the equipment did not include a probe It was my probe, also not seen for many years, which demonstrated the arterial obstruction

In 1929 I contributed to my hospital journal a list of "signposts" for the guidance of students, remembering to add that signposts are sometimes misleading "Whatever your medical hobby, be always a general practitioner" was one I have always tried to be this and I held all save one of the house and special-department appointments at my hospital, besides doing jobs at various special hospitals later I have never appreciated the habit of mind which permits a gynæcologist to crow because correctly or not he diagnoses tabes dorsalis, or an orthopædic surgeon to admit, with some pride, that auricular fibrillation is entirely outside his professional vision These chaps ought to put in half their annual holiday doing country practice

* * *

The difficulty of securing an adequate and varied diet in war time troubles everyone It must be particularly irksome for the small householder, who has to try to make the most of limited coupon resources, but even hospitals are not without their woes It is true that in the main food authorities are sympathetic to their special needs and willing enough to allow a certain measure of advance purchase against subsequent account, but there is an overriding moral obligation to adhere to rationing standards as they affect the population as a whole, subject, of course, to the special medical requirements of any particular case The trouble is that no reasonable interpretation of this latitude will stretch sufficiently far to permit the supply of unlimited quantities of meat, bacon, eggs and other rationed foodstuffs , nor is it necessary that it should An inheritance can sometimes carry with it troublesome implications and to be housed in a building that once enjoyed some reputation as a resort of epicures may convey to the world at large, and to potential customers, the suggestion that the place is still a sort of country club, with cuisine as of yore, and with a horizon untouched by rationing or any other ill the times—the perfect setting, in fact for a golfing liday as we used to know it

Many of our patients are not particularly ill but that t does not make them any easier to nurse Some are ry willing to be spoiled, and some being human, willing ough to grumble It is notorious that officers are far ore difficult to care for than other ranks (not of course l officers, for many of them are eminently reasonable) e often wonder how far the hordes of County visitors ho haunt our corridors contribute to the contentment the hospital We have repeatedly had occasion to spect that their intromissions were not an unmixed essing They are willing enough to take an occasional ficer patient home to lunch, and doubtless to do him ery well bringing to his menu on that occasion grouse nd a variety of other things not always obtainable by dinary mortals It is an easy step from that to commiseration with the hard lot that deprives the poor boys their sherry and their caviare, and an easy step to infer hat there must be something wrong with the standards a hospital that is content with simpler fare When ith their units, officers participate in such mess arrangements as they collectively wish to adopt and it is often pen to them to supplement their diet from sources not ormally available either to the man in the street or to ivilian hospitals It is not surprising that they notice he transition that hospitalisation is apt to involve But it is difficult to believe that reasonably adequate plain fare for two weeks, or even three undermines their physique to any appreciable extent, or does them any eal moral or physical harm Many people doing quite lot of active work would think they were being very well ed on a regime that brought to them (to take a typical lay) at 6 30 A M a cup of tea , at 8 30 A M breakfast porridge grilled tomatoes on toast, rolls , at 11 A M Bovril, cocoa or milk , at 1 P M lunch curried mutton, potatoes, baked rice peaches and custard, biscuits and cheese at 4 P M tea, white and brown bread scones butter, jam , at 6 45 P M dinner potato soup, roasted chicken, bread sauce, green peas and potatoes, steamed pudding and custard, coffee , and at 9 P M Ovaltine, cocoa or milk That does not sound unbearable in the summer of 1941 It is, indeed, a question how far it is desirable that the same base hospital should cater for both officers and men except under conditions of real emergency There might well prove to be advantages n segregating officer patients in a hospital of their own under conditions and discipline compatible with their status and enabling them to make such communal arrangements as they please to eke out official rations, n the knowledge that they would then be able to supplement their diet to their hearts' content That might conceivably breed real contentment

* * *

These moral jerks at 7 55 A M still follow the old accustomed lines, girding the national spirit for war, hardening the erector spinæ of resolve, the pectorals of perseverance, and quite right too Perhaps it would never do to be experimental like this —

“ I want to talk to you this morning about those much maligned but valuable biological virtues called Jealousy and Envy, which I need hardly remind you are closely related to the perfectly respectable Zeal and Insight It is true that throughout the ages they have been held up to scorn and ridicule, but that is because the position of all preachers and other leaders is directly threatened by them You will notice they very rarely attack the ibling their favourite, Ambition Yet these are valuable qualities , they tend to haul any man who seeks to get above his fellows back to the common mean , they make him watch his step lest he get too far ahead , they are Nature's thermostat, the dictator's bane Hitler, by killing off the people who might be actuated by these useful qualities—a most unnatural crime—has placed Germany in a precarious biological condition, mass of people obedient to the unsafeguarded will or whim of one unbalanced man ”

I don't think I ever guessed at the mechanism until I aw it in operation in larval form Before the war I went for a number of years to a large mixed boys' camp nd every year the same thing happened The camp tarted off harmoniously, if shyly, under adult direction Apparently leaders who are grossly dissimilar in age from he led don't evoke jealously (Pitt and Pétain) Then about the third day the camp chief gave his celebrated little talk on “ leadership,” holding up for the boys' emulation a projection figure of a fearless hard-working, self-sacrificing, loyal, yet withal modest youth Thereafter the camp got much more interesting for it became not so much a competition in these qualities as a competition in the display of them, a very different matter The display of modesty, for instance needed great subtlety, or possibly a friend who'd act as publicity agent It was from observation at this most amusing camp that I found out several things about envy and jealousy in relation to leadership, which are doubly true of adults, for these virtues don't really come to their prime till the fourth and fifth decades the leadership age Envy and jealousy are much stronger in the friends and associates of a leader than in strangers to him , if one could measure these things up I expect they would be found to increase with the cube of the friendship When they are very strong, as among a group of intimates, the leader must be one of them who is well below mediocrity, or he may even have to be chosen from outside the group The mechanism is abolished when self-preservation is in question—envy and jealousy vanish on the threat of real danger Leaders then have the loyalty even of their friends (Chamberlain September, 1938 , Churchill, 1940–?)

ASSOCIATION OF CLINICAL PATHOLOGISTS

About 60 members and guests attended a meeting on July 19 of the association in the pathological department and St Catherine's College, Cambridge

Dr J F Gaskell described 7 cases of fatal acute pancreatitis in Cambridge between 1932 and 1934 The patients were in vigorous health but died within a few hours, in several cases shortly after a full meal At necropsy, done usually within 24 hours acute hæmorrhagic and even necrotic pancreatitis, apparently of antemortem origin, was found No association between the cases could be traced and no significant microbes were found A footballer died on the field the suggestion being that the head of the pancreas had been squeezed against the spine by another player's knees

Dr G A Harrison and Mr L E R Picken Ph D , described and demonstrated the preparation of blood-serum for transfusion (*Lancet*, 1941, 1, 536) Ordinary dry blood bottles were used and about 47% yield of serum was obtained The resultant serum remained clear at room temperature Among 102 transfusions, pyrexia with rigor occurred once and without rigor four times—that is, reactions occurred in about 5% On the assumption that the body contains 10 pints of blood and that a hæmorrhage of 6 pints is the largest compatible with survival, the maximum amount of serum that could be required even in the worst cases would be 3 pints—i e , half the volume of blood lost (*Ibid* p 685) In most transfusions one bottle of serum had been given Defibrinated blood was also prepared 30 c cm of glass beads shaken in the blood gave good defibrination (*Ibid*, p 405) If the blood were not used the serum could be recovered later

Dr A M Barrett pointed out the importance of details of technique in deciding titre in the Paul-Bunnell test for glandular fever Horse red cells give a somewhat higher titre than sheep cells Of 100 normal human sera none agglutinated sheep cells at 1/80, 4 gave titre of 1/80 or slightly higher with horse cells Of 27 cases of glandular fever 17 gave a titre of 1/640 or slightly less with sheep cells, 10 had a higher titre With horse cells 11 gave 1/640 or less and 16 showed a higher titre The slight titre in normal sera can be abolished by absorption with Forssman antigen (guineapig kidney) whereas ox cells will absorb the true glandular-fever hæmagglutinin

Dr S C Dyke showed curves of blood-counts during trichiniasis (*Lancet*, July 19, 1941 p 69) The rise in the total white cells may not start for about a week , it reaches in the average case about 18,000 at three weeks and drops to 9000 at seven weeks, with a temporary secondary rise to 19 000 at about ten weeks This curve runs parallel to the eosinophil curve since it is the eosinophil increase that mainly causes the leucocytosis During the early reduction or absence of eosinophil cells, eosinophil granules may be found in the poly-year anatomy, physiology and biochemistry for eighteen months , and then clinical work The early part of the clinical years, however, was spent largely in the lecture-rooms The student attended lectures and demonstrations throughout the day in all the subjects of his syllabus and did not "take a case" in the manner of the English ward clerk until he had reached his second or third year of clinical work The effect of this was to give him an exceedingly sound background of theoretical knowledge, which served him well later in life , but it was heavy going His final years were spent in getting practical experience not in one but in several hospitals The final examination was very long, often occupying two months or more, and divided according to subjects into more than twelve sections surgery, medicine, obstetrics, gynæcology, hygiene, pharmacology, surgical anatomy, pathology, ear, nose and throat diseases, ophthalmology, psychiatry, pædiatrics and forensic medicine Hygiene covered a wide variety of subjects, including social and prophylactic medicine, public health, insurance medicine and bacteriology The hygiene course occupied four hours weekly for a year and was followed by a practical course in public health in which house construction sanitation and water-testing were studied and visits were paid to sewage farms, sanitary institutes, water works and public-health departments Thus the student received a much more thorough grounding in the social aspects of medicine than his English contemporary He was also taught pharmacology much more thoroughly, lectures on toxicology and the action, chemistry and biological effect of drugs being given throughout the period of clinical teaching , prescribing was taught separately in a short course

Just before the Nazi regime began, the medical curriculum was under discussion and experimental changes were being made in it These reforms placed more emphasis on the practical side of training and less on detailed scientific instruction The balancing of the various specialties roused as much controversy there as here every exponent believed his subject to deserve a prominent place in the final examination With the coming of the Nazis and the preparations for war these academic dissensions were cut short , the government insisted that subjects useful to the military organisation should be given precedence Doctors were to be trained for the army and the air force , and Hitler's hobby, "race biology," ousted a growing interest in prophylactic medicine The emphasis thus swung towards the practical side lectures were replaced by practical classes and students were brought early into contact with patients This was in accordance with the Nazi principle of discouraging too much spontaneous thought and they carried it through with their usual fervour Curiously enough it had the effect of bringing the German curriculum—which had previously been overweighted by science and theory—more into line with the British and French type of education Every medical student was obliged to act as a nurse in hospital for some months before beginning his clinical work—a piece of practical experience which he probably found invaluable

THE SOLDIER'S DEFENCE AND THE PUBLIC'S ATTITUDE*

W. CLIFFORD M. SCOTT, M.D. Toronto
PHYSICIAN TO THE LONDON CLINIC OF PSYCHO-ANALYSIS;
PSYCHIATRIC SPECIALIST, E.M.S.

THE soldier's commonest single defence against more serious psychiatric illness is a complaint that he is afraid of some aspect of the situation which war has brought about. Common variations of this complaint are that he is afraid of becoming ill or that he is already ill. The public accepts physical illness, injury and abnormal fear as understandable war casualties. Fear of a situation which is frequently described as horrible or intolerable is now an acceptable type of war casualty. This is due to a change in the public's attitude during the past generation.

Before the last war the valorous soldier was considered to be fearless. To fear that the enemy was too dangerous to attack was cowardice and to show it might turn his superior officers into assailants more dangerous than the enemy. Some soldiers were shot. Owing perhaps to the size of the conscript armies of the last war the problem of fear was forced on the military physician. Gradually the belief that war stimulated instincts—among them a self-preservative instinct—became common. It was accepted that thwarting this instinct led invariably to a fear reaction, even though in some people this reaction might be slight. The problem of treatment became a problem of keeping this fear reaction within such normal bounds that there was no interference with social duty. The stimulus to the self-preservative instinct was considered to be the likelihood of death. This widely accepted psychopathology was discussed both inside and outside the medical profession and was found among those who gave evidence before the War Office committee of inquiry into shell shock, which reported in 1922.

Since the last war two lines of research have produced a wide gulf separating the attitude of the general public and the general medical world from that of many psychiatrists. This gulf is as wide in many ways as that present during the early years of the last war when shell-shock was still only a neurological problem and cowardice only a crime. The first type of research consisted of behaviouristic studies of infants in an attempt to identify the nature and development of early fear reactions, and the second of psycho-analytic studies into the relation of the symptoms of fear to previous emotional states. Observation of infant development, both by those neurologically and those psychologically oriented, has not provided evidence that there is a primary pattern of fear reaction in infancy. No single fear reaction can be identified in infancy which contains within it all or most of the signs and symptoms of fear reactions in later life. Studies of the startle reaction have led to the conclusion that there may be a short reflex phase followed by a variety of secondary reactions. The early aspects of what may later become fainting reactions and stupor reactions have been found to be quite complex from the time they can be identified. Perhaps the safest conclusion to be drawn from the behaviouristic studies is that evidence of primary satisfaction and primary rage are the only easily identified primary reactions. Fear and sorrow reactions appear even at their onset to be more complicated and derivative than was previously held.

Psycho-analytic studies have developed rapidly, especially since the publication by Freud in 1926 of his book "Inhibition, Symptom and Anxiety." Work in this country, especially with children and the mild psychotic reactions in adults, has clarified some of the problems involved. Freud related the symptoms of fear to symptoms of other types and to previous traumata. By trauma he meant a situation producing pain or frustration of instinctual need. He showed that the theoretical basis of anxiety neurosis as formulated by him in 1895 was largely superseded. His newer conception was that fear was a signal—which sometimes could be considered abnormal and sometimes normal—meaning that something had to be done or worse would ensue. The content of the signal (the symptoms of the fear) was a partial memory of a state which had been present during a previous trauma. This formulation led to an increase in our knowledge of the way the ego developed under the influence of fear, and to a more detailed understanding of types of neurotic and psychotic fear. But the older conception, that repression of instinctive activity leads to transformation of the repressed instinctual energy into something appearing in consciousness as fear, is still too commonly used in treatment. The widespread neglect of the work done in the past fifteen years must be in itself an attempt to deny the complexity of what goes on unconsciously. In looking back it is difficult to understand why signal fear was so long unformulated. Such expressions as "I was afraid I'd laugh," "I was afraid I'd cry," "I was afraid I'd lose my temper," "I was afraid he'd know I was afraid," "I was afraid I'd frighten him" show that few doubt that one can be frightened consciously of one's own impulses. These situations are expressed even more openly in such phrases as "I wanted to laugh but I was afraid to," "I wanted to cry but I was afraid to." That one could be frightened of one's unconscious impulses remained for long undiscovered; the more unconscious the content of the fear the more likely are we to use the word anxiety instead of fear in describing it. Perhaps there are many psychopathological truths hidden behind current idioms which are as yet neither utilised nor consciously understood.

THREE EXAMPLES OF FEAR

If common sayings mentioning fear express an unconscious instead of a conscious content they disclose widely different psychopathological problems. When a patient says he is afraid he may be unconsciously on the verge of becoming excited in a way which got him into trouble on some previous occasion, and his symptoms of fear may be a partial although unrecognised memory of this experience.

CASE 1.—A territorial soldier aged 26, who had served satisfactorily for 15 months in an anti-aircraft battery since the outbreak of war, became afraid that he would show fear by trembling. He knew that his officer was thinking of recommending him for a commission. He went sick. During treatment it became apparent that he was frightened of becoming overwhelmed by outbursts of enthusiastic kindly thoughts about the enemy. In the past he had often influenced people who had tended to frustrate him by becoming ingratiating, and by exploiting a well developed capacity for being enthusiastically pleasant. Tremor was the "fear signal." It was a partial memory of trembling with happy excitement. He had good reason to believe that the wish to ingratiate the enemy would lead to difficulties similar to, or greater than, those he had experienced in the past when his enthusiasm had not proved as acceptable as he had hoped.

A patient may be frightened of unconscious wishes to grieve.

CASE 2.—A soldier of the last war, now aged 45, who fought successfully through a recent campaign except for 4 hours' unconsciousness after a bomb-burst nearby. Some time after returning to this country he became generally frightened, especially concerning his sight, which he said was failing. During treatment he discovered a wish to cry about a situation which was developing at home. His wife had begun to work and he thought she was neglecting their children. Before treatment he had only felt annoyed at his wife's behaviour. His fear and difficulty with vision had begun when he had, for the first time, nearly cried while writing to his wife. His sorrow was connected not only with his neglected children but also with memories of being neglected in childhood and with feelings that he had been neglected in his unit.

A patient may be frightened of his unconscious rage.

CASE 3.—A man of 23 who had stammered at times throughout his life was annoyed when not called up into the corps for which he considered himself most suited. He became ill at

TREATMENT OF BURNS IN SWITZERLAND

TANNING methods in the treatment of burns receive enthusiastic support from Major Henschen of the University Clinic at Basle (*Helv med Acta*, April, 1941, p 77) It may well be that the tragic after results of this treatment in the deeper degrees of burning have not come to his notice but it comes as rather a shock to find that it is precisely in those degrees of burn in which the use of tannic acid is in this country regarded with so much misgiving that he most strongly advises it Henschen follows Dupuytren's historic classification of burns into six degrees For the first two—erythema and blistering—he considers tanning methods pointless Even in third-degree burns he would restrict its use to cases in which, over a large burnt area, there are only apparent a few scattered islands of epithelium In the fourth degree, however, he believes he has the main indication for tanning Here all the epithelium is destroyed, and British plastic surgeons might be expected to shudder at the very mention of the formation of a tannic scar on the deep tissues In two other directions Henschen is in more direct agreement with us He advocates the prophylactic use of sulphonamide drugs in the prevention of septicæmia in burns, and he believes in early skin-grafting to prevent contracture of scars and consequent crippling and deformity He suggests the local treatment of burns by the application of 5–15 g of sulphonamide powder, mixed with some form of anæsthetic powder to lessen the pain it might produce, but does not mention any personal experience of the effects The clean granulating wound he skin-grafts, believing that the graft has a direct stimulating effect on the deep healing of the wound He evidently prefers the Thiersch graft where the area to be covered is not too extensive, because, as he puts it, the thinner the graft the greater its vitality For larger wounds he uses a thicker graft, which is intermediate between the thin Thiersch and the deeper Wolfe graft He stretches the graft out on a towel rung out in saline solution and converts it into a type of "sieve" graft with multiple incisions In this way he allows discharge from the granulating area to escape through the graft and finds that the graft itself can more easily be stretched to the size and shape of the area to be covered

Births, Marriages and Deaths

BIRTHS

BARWELL—On Aug 16 at Woking the wife of Surgeon Lieutenant T E Barwell R N V R—a daughter

BEDFORD—On Aug 21 at Aldershot, the wife of Lieut Colonel Evan Bedford R A M C—a son

BELL—On Aug 22 at North Shields to Dr Jean Margery Bell (née Cass) wife of the Rev R G Bell—a son

CAMPBELL—On Aug 20 at Tettenhall the wife of Dr A H Campbell of West Town Somerset—a son

DODS—On Aug 18 at Amersham Bucks the wife of Captain A S Dods, R A M C—a son

IRVINE—On Aug 22 at Henley on Thames the wife of Major K Neville Irvine, R A M C—a son

KENDALL—On Aug 16, at Aberdeen the wife of Surgeon Commander A Wallis Kendall R N V R—a son

THE SOLDIER'S DEFENCE AND THE PUBLIC'S ATTITUDE *

W CLIFFORD M. SCOTT, M D Toronto
PHYSICIAN TO THE LONDON CLINIC OF PSYCHO ANALYSIS;
PSYCHIATRIC SPECIALIST, E.M.S

THE soldier's commonest single defence against more serious psychiatric illness is a complaint that he is afraid of some aspect of the situation which war has brought about Common variations of this complaint are that he is afraid of becoming ill or that he is already ill. The public accepts physical illness, injury and abnormal fear as understandable war casualties Fear of a situation which is frequently described as horrible or intolerable is now an acceptable type of war casualty. This is due to a change in the public's attitude during the past generation.

Before the last war the valorous soldier was considered to be fearless To fear that the enemy was too dangerous to attack was cowardice and to show it might turn his superior officers into assailants more dangerous than the enemy Some soldiers were shot Owing perhaps to the size of the conscript armies of the last war the problem of fear was forced on the military physician. Gradually the belief that war stimulated instincts—among them a self-preservative instinct—became common. It was accepted that thwarting this instinct led invariably to a fear reaction, even though in some people this reaction might be slight The problem of treatment became a problem of keeping this fear reaction within such normal bounds that there was no interference with social duty. The stimulus to the self-preservative instinct was considered to be the likelihood of death This widely accepted psychopathology was discussed both inside and outside the medical profession and was found among those who gave evidence before the War Office committee of inquiry into shell shock, which reported in 1922

Since the last war two lines of research have produced a wide gulf separating the attitude of the general public and the general medical world from that of many psychiatrists This gulf is as wide in many ways as that present during the early years of the last war when shell-shock was still only a neurological problem and cowardice only a crime. The first type of research consisted of behaviouristic studies of infants in an attempt to identify the nature and development of early fear reactions and the second of psycho-analytic studies into the relation of the symptoms of fear to previous emotional states Observation of infant development, both by those neurologically and those psychologically oriented has not provided evidence that there is a primary pattern of fear reaction in infancy. No single fear reaction can be identified in infancy which contains within it all or most of the signs and symptoms of fear reactions in later life Studies of the startle reaction have led to the conclusion that there may be a short reflex phase followed by a variety of secondary reactions The early aspects of what may later become fainting reactions and stupor reactions have been found to be quite complex from the time they can be identified Perhaps the safest conclusion to be drawn from the behaviouristic studies is that evidence of primary satisfaction and primary rage are the only easily identified primary reactions Fear and sorrow reactions appear even at their onset to be more complicated and derivative than was previously held

Psycho-analytic studies have developed rapidly especially since the publication by Freud in 1926 of his book "Inhibition Symptom and Anxiety" Work in this country, especially with children and the mild psychotic reactions in adults has clarified some of the problems involved Freud related the symptoms of fear to symptoms of other types and to previous traumata By trauma he meant a situation producing pain or frustration of instinctual need He showed that the theoretical basis of anxiety neurosis as formulated by him in 1895 was largely superseded His newer conception was that fear was a signal—which sometimes could be considered abnormal and sometimes normal—meaning that something had to be done or worse would ensue. The content of the signal (the symptoms of the fear) was a partial memory of a state which had been present during a previous trauma This formulation led to an increase in our knowledge of the way the ego developed under the influence of fear, and to a more detailed understanding of types of neurotic and psychotic fear. But the older conception that repression of instinctive activity leads to transformation of the repressed instinctual energy into something appearing in consciousness as fear, is still too commonly used in treatment The widespread neglect of the work done in the past fifteen years must be, in itself, an attempt to deny the complexity of what goes on unconsciously In looking back it is difficult to understand why signal fear was so long unformulated Such expressions as "I was afraid I'd laugh," "I was afraid I'd cry," "I was afraid I'd lose my temper." "I was afraid he'd know I was afraid" "I was afraid I'd frighten him" show that few doubt that one can be frightened consciously of one's own impulses These situations are expressed even more openly in such phrases as "I wanted to laugh but I was afraid to" "I wanted to cry but I was afraid to" That one could be frightened of one's unconscious impulses remained for long undiscovered; the more unconscious the content of the fear the more likely are we to use the word anxiety instead of fear in describing it Perhaps there are many psychopathological truths hidden behind current idioms which are as yet neither utilised nor consciously understood

THREE EXAMPLES OF FEAR

If common sayings mentioning fear express an unconscious instead of a conscious content they disclose widely different psychopathological problems. When a patient says he is afraid he may be unconsciously on the verge of becoming excited in a way which got him into trouble on some previous occasion and his symptoms of fear may be a partial although unrecognised memory of this experience

CASE 1—A territorial soldier aged 26, who had served satisfactorily for 15 months in an anti-aircraft battery since the outbreak of war, became afraid that he would show fear by trembling He knew that his officer was thinking of recommending him for a commission. He went sick. During treatment it became apparent that he was frightened of becoming overwhelmed by outbursts of enthusiastic kindly thoughts about the enemy In the past he had often influenced people who had tended to frustrate him by becoming ingratiating, and by exploiting a well-developed capacity for being enthusiastically pleasant. Tremor was the fear signal" It was a partial memory of trembling with happy excitement He had good reason to believe that the wish to ingratiate the enemy would lead to difficulties similar to, or greater than, those he had experienced in the past when his enthusiasm had not proved as acceptable as he had hoped.

A patient may be frightened of unconscious wishes to grieve.

CASE 2—A soldier of the last war, now aged 45, who fought successfully through a recent campaign except for 4 hours' unconsciousness after a bomb-burst nearby. Some time after returning to this country he became generally frightened, especially concerning his sight, which he said was failing During treatment he discovered a wish to cry about a situation which was developing at home His wife had begun to work and he thought she was neglecting their children. Before treatment he had only felt annoyed at his wife's behaviour His fear and difficulty with vision had begun when he had for the first time, nearly cried while writing to his wife His sorrow was connected not only with his neglected children but also with memories of being neglected in childhood and with feelings that he had been neglected in his unit

A patient may be frightened of his unconscious rage.

CASE 3—A man of 23 who had stammered at times throughout his life was annoyed when not called up into the corps for which he considered himself most suited. He became ill at

TREATMENT OF BURNS IN SWITZERLAND

TANNING methods in the treatment of burns receive enthusiastic support from Major Henschen of the University Clinic at Basle (*Helv med Acta*, April, 1941 p 77) It may well be that the tragic after results of this treatment in the deeper degrees of burning have not come to his notice but it comes as rather a shock to find that it is precisely in those degrees of burn in which the use of tannic acid is in this country regarded with so much misgiving that he most strongly advises it Henschen follows Dupuytren's historic classification of burns into six degrees For the first two—erythema and blistering—he considers tanning methods pointless Even in third-degree burns he would restrict its use to cases in which over a large burnt area there are only apparent a few scattered islands of epithelium In the fourth degree however, he believes he has the main indication for tanning Here all the epithelium is destroyed, and British plastic surgeons might be expected to shudder at the very mention of the formation of a tannic scar on the deep tissues In two other directions Henschen is in more direct agreement with us He advocates the prophylactic use of sulphonamide drugs in the prevention of septicæmia in burns, and he believes in early skin-grafting to prevent contracture of scars and consequent crippling and deformity He suggests the local treatment of burns by the application of 5–15 g of sulphonamide powder, mixed with some form of anæsthetic powder to lessen the pain it might produce but does not mention any personal experience of the effects The clean granulating wound he skin-grafts, believing that the graft has a direct stimulating effect on the deep healing of the wound He evidently prefers the Thiersch graft where the area to be covered is not too extensive, because, as he puts it, the thinner the graft the greater its vitality For larger wounds he uses a thicker graft, which is intermediate between the thin Thiersch and the deeper Wolfe graft He stretches the graft out on a towel wrung out in saline solution and converts it into a type of "sieve" graft with multiple incisions In this way he allows discharge from the granulating area to escape through the graft and finds that the graft itself can more easily be stretched to the size and shape of the area to be covered

THE SOLDIER'S DEFENCE AND THE PUBLIC'S ATTITUDE*

W. CLIFFORD M. SCOTT, M.D. Toronto
PHYSICIAN TO THE LONDON CLINIC OF PSYCHO-ANALYSIS;
PSYCHIATRIC SPECIALIST, E.M.S.

THE soldier's commonest single defence against more serious psychiatric illness is a complaint that he is afraid of some aspect of the situation which war has brought about. Common variations of this complaint are that he is afraid of becoming ill or that he is already ill. The public accepts physical illness, injury and abnormal fear as understandable war casualties. Fear of a situation which is frequently described as horrible or intolerable is now an acceptable type of war casualty. This is due to a change in the public's attitude during the past generation.

Before the last war the valorous soldier was considered to be fearless. To fear that the enemy was too dangerous to attack was cowardice and to show it might turn his superior officers into assailants more dangerous than the enemy. Some soldiers were shot. Owing perhaps to the size of the conscript armies of the last war the problem of fear was forced on the military physician. Gradually the belief that war stimulated instincts—among them a self-preservative instinct—became common. It was accepted that thwarting this instinct led invariably to a fear reaction, even though in some people this reaction might be slight. The problem of treatment became a problem of keeping this fear reaction within such normal bounds that there was no interference with social duty. The stimulus to the self-preservative instinct was considered to be the likelihood of death. This widely accepted psychopathology was discussed both inside and outside the medical profession and was found among those who gave evidence before the War Office committee of inquiry into shell shock, which reported in 1922.

Since the last war two lines of research have produced a wide gulf separating the attitude of the general public and the general medical world from that of many psychiatrists. This gulf is as wide in many ways as that present during the early years of the last war when shell-shock was still only a neurological problem and cowardice only a crime. The first type of research consisted of behaviouristic studies of infants in an attempt to identify the nature and development of early fear reactions, and the second of psycho-analytic studies into the relation of the symptoms of fear to previous emotional states. Observation of infant development, both by those neurologically and those psychologically oriented, has not provided evidence that there is a primary pattern of fear reaction in infancy. No single fear reaction can be identified in infancy which contains within it all or most of the signs and symptoms of fear reactions in later life. Studies of the startle reaction have led to the conclusion that there may be a short reflex phase followed by a variety of secondary reactions. The early aspects of what may later become fainting reactions and stupor reactions have been found to be quite complex from the time they can be identified. Perhaps the safest conclusion to be drawn from the behaviouristic studies is that evidence of primary satisfaction and primary rage are the only easily identified primary reactions. Fear and sorrow reactions appear even at their onset to be more complicated and derivative than was previously held.

Psycho-analytic studies have developed rapidly, especially since the publication by Freud in 1926 of his book "Inhibition, Symptom and Anxiety." Work in this country, especially with children and the mild psychotic reactions in adults, has clarified some of the problems involved. Freud related the symptoms of fear to symptoms of other types and to previous traumata. By trauma he meant a situation producing pain or frustration of instinctual need. He showed that the theoretical basis of anxiety neurosis as formulated by him in 1895 was largely superseded. His newer conception was that fear was a signal—which sometimes could be considered abnormal and sometimes normal—meaning that something had to be done or worse would ensue. The content of the signal (the symptoms of the fear) was a partial memory of a state which had been present during a previous trauma. This formulation led to an increase in our knowledge of the way the ego developed under the influence of fear, and to a more detailed understanding of types of neurotic and psychotic fear. But the older conception, that repression of instinctive activity leads to transformation of the repressed instinctual energy into something appearing in consciousness as fear, is still too commonly used in treatment. The widespread neglect of the work done in the past fifteen years must be, in itself, an attempt to deny the complexity of what goes on unconsciously. In looking back it is difficult to understand why signal fear was so long unformulated. Such expressions as "I was afraid I'd laugh," "I was afraid I'd cry," "I was afraid I'd lose my temper," "I was afraid he'd know I was afraid," "I was afraid I'd frighten him" show that few doubt that one can be frightened consciously of one's own impulses. These situations are expressed even more openly in such phrases as "I wanted to laugh but I was afraid to" "I wanted to cry but I was afraid to." That one could be frightened of one's unconscious impulses remained for long undiscovered; the more unconscious the content of the fear the more likely are we to use the word anxiety instead of fear in describing it. Perhaps there are many psychopathological truths hidden behind current idioms which are as yet neither utilised nor consciously understood.

THREE EXAMPLES OF FEAR

If common sayings mentioning fear express an unconscious instead of a conscious content they disclose widely different psychopathological problems. When a patient says he is afraid, he may be unconsciously on the verge of becoming excited in a way which got him into trouble on some previous occasion and his symptoms of fear may be a partial although unrecognised memory of this experience.

CASE 1.—A territorial soldier aged 26, who had served satisfactorily for 15 months in an anti-aircraft battery since the outbreak of war, became afraid that he would show fear by trembling. He knew that his officer was thinking of recommending him for a commission. He went sick. During treatment it became apparent that he was frightened of becoming overwhelmed by outbursts of enthusiastic kindly thoughts about the enemy. In the past he had often influenced people who had tended to frustrate him by becoming ingratiating, and by exploiting a well developed capacity for being enthusiastically pleasant. Tremor was the "fear signal." It was a partial memory of trembling with happy excitement. He had good reason to believe that the wish to ingratiate the enemy would lead to difficulties similar to, or greater than, those he had experienced in the past when his enthusiasm had not proved as acceptable as he had hoped.

A patient may be frightened of unconscious wishes to grieve.

CASE 2.—A soldier of the last war, now aged 45, who fought successfully through a recent campaign except for 4 hours' unconsciousness after a bomb-burst nearby. Some time after returning to this country he became generally frightened, especially concerning his sight, which he said was failing. During treatment he discovered a wish to cry about a situation which was developing at home. His wife had begun to work and he thought she was neglecting their children. Before treatment he had only felt annoyed at his wife's behaviour. His fear and difficulty with vision had begun when he had, for the first time, nearly cried while writing to his wife. His sorrow was connected not only with his neglected children but also with memories of being neglected in childhood and with feelings that he had been neglected in his unit.

A patient may be frightened of his unconscious rage.

CASE 3.—A man of 23 who had stammered at times throughout his life was annoyed when not called up into the corps for which he considered himself most suited. He became ill at

TREATMENT OF BURNS IN SWITZERLAND

TANNING methods in the treatment of burns receive enthusiastic support from Major Henschen of the University Clinic at Basle (*Helv med Acta*, April, 1941 p 77) It may well be that the tragic after results of this treatment in the deeper degrees of burning have not come to his notice but it comes as rather a shock to find that it is precisely in those degrees of burn in which the use of tannic acid is in this country regarded with so much misgiving that he most strongly advises it Henschen follows Dupuytren's historic classification of burns into six degrees For the first two—erythema and blistering—he considers tanning methods pointless Even in third-degree burns he would restrict its use to cases in which, over a large burnt area, there are only apparent a few scattered islands of epithelium In the fourth degree, however, he believes he has the main indication for tanning Here all the epithelium is destroyed, and British plastic surgeons might be expected to shudder at the very mention of the formation of a tannic scar on the deep tissues In two other directions Henschen is in more direct agreement with us He advocates the prophylactic use of sulphonamide drugs in the prevention of septicæmia in burns, and he believes in early skin-grafting to prevent contracture of scars *and consequent crippling and deformity He suggests* the local treatment of burns by the application of 5–15 g of sulphonamide powder, mixed with some form of anæsthetic powder to lessen the pain it might produce, but does not mention any personal experience of the effects The clean granulating wound he skin-grafts, believing that the graft has a direct stimulating effect on the deep healing of the wound He evidently prefers the Thiersch graft where the area to be covered is not too extensive, because, as he puts it, the thinner the graft the greater its vitality For larger wounds he uses a thicker graft, which is intermediate between the thin Thiersch and the deeper Wolfe graft He stretches the graft out on a towel rung out in saline solution and converts it into a type of "sieve" graft with multiple incisions In this way he allows discharge from the granulating area to escape through the graft and finds that the graft itself can more easily be stretched to the size and shape of the area to be covered

THE SOLDIER'S DEFENCE AND THE PUBLIC'S ATTITUDE *

W. CLIFFORD M. SCOTT, M.D. Toronto
PHYSICIAN TO THE LONDON CLINIC OF PSYCHO-ANALYSIS;
PSYCHIATRIC SPECIALIST, E.M.S.

THE soldier's commonest single defence against more serious psychiatric illness is a complaint that he is afraid of some aspect of the situation which war has brought about. Common variations of this complaint are that he is afraid of becoming ill or that he is already ill. The public accepts physical illness, injury and abnormal fear as understandable war casualties. Fear of a situation which is frequently described as horrible or intolerable is now an acceptable type of war casualty. This is due to a change in the public's attitude during the past generation.

Before the last war the valorous soldier was considered to be fearless. To fear that the enemy was too dangerous to attack was cowardice and to show it might turn his superior officers into assailants more dangerous than the enemy. Some soldiers were shot. Owing perhaps to the size of the conscript armies of the last war the problem of fear was forced on the military physician. Gradually the belief that war stimulated instincts—among them a self-preservative instinct—became common. It was accepted that thwarting this instinct led invariably to a fear reaction even though in some people this reaction might be slight. The problem of treatment became a problem of keeping this fear reaction within such normal bounds that there was no interference with social duty. The stimulus to the self-preservative instinct was considered to be the likelihood of death. This widely accepted psychopathology was discussed both inside and outside the medical profession and was found among those who gave evidence before the War Office committee of inquiry into shell shock, which reported in 1922.

Since the last war two lines of research have produced a wide gulf separating the attitude of the general public and the general medical world from that of many psychiatrists. This gulf is as wide in many ways as that present during the early years of the last war when shell-shock was still only a neurological problem and cowardice only a crime. The first type of research consisted of behaviouristic studies of infants in an attempt to identify the nature and development of early fear reactions, and the second of psycho-analytic studies into the relation of the symptoms of fear to previous emotional states. Observation of infant development, both by those neurologically and those psychologically oriented, has not provided evidence that there is a primary pattern of fear reaction in infancy. No single fear reaction can be identified in infancy which contains within it all or most of the signs and symptoms of fear reactions in later life. Studies of the startle reaction have led to the conclusion that there may be a short reflex phase followed by a variety of secondary reactions. The early aspects of what may later become fainting reactions and stupor reactions have been found to be quite complex from the time they can be identified. Perhaps the safest conclusion to be drawn from the behaviouristic studies is that evidence of primary satisfaction and primary rage are the only easily identified primary reactions. Fear and sorrow reactions appear even at their onset to be more complicated and derivative than was previously held.

Psycho-analytic studies have developed rapidly, especially since the publication by Freud in 1926 of his book "Inhibition, Symptom and Anxiety." Work in this country, especially with children and the mild psychotic reactions in adults has clarified some of the problems involved. Freud related the symptoms of fear to symptoms of other types and to previous traumata. By trauma he meant a situation producing pain or frustration of instinctual need. He showed that the theoretical basis of anxiety neurosis as formulated by him in 1895 was largely superseded. His newer conception was that fear was a signal—which sometimes could be considered abnormal and sometimes normal—meaning that something had to be done or worse would ensue. The content of the signal (the symptoms of the fear) was a partial memory of a state which had been present during a previous trauma. This formulation led to an increase in our knowledge of the way the ego developed under the influence of fear, and to a more detailed understanding of types of neurotic and psychotic fear. But the older conception, that repression of instinctive activity leads to transformation of the repressed instinctual energy into something appearing in consciousness as fear, is still too commonly used in treatment. The widespread neglect of the work done in the past fifteen years must be, in itself, an attempt to deny the complexity of what goes on unconsciously. In looking back it is difficult to understand why signal fear was so long unformulated. Such expressions as "I was afraid I'd laugh," "I was afraid I'd cry," "I was afraid I'd lose my temper" "I was afraid he'd know I was afraid," "I was afraid I'd frighten him" show that few doubt that one can be frightened *consciously of one's own impulses*. These situations are expressed even more openly in such phrases as "I wanted to laugh but I was afraid to" "I wanted to cry but I was afraid to." That one could be frightened of one's unconscious impulses remained for long undiscovered; the more unconscious the content of the fear the more likely are we to use the word anxiety instead of fear in describing it. Perhaps there are many psychopathological truths hidden behind current idioms which are as yet neither utilised nor consciously understood.

THREE EXAMPLES OF FEAR

If common sayings mentioning fear express an unconscious instead of a conscious content they disclose widely different psychopathological problems. When a patient says he is afraid, he may be unconsciously on the verge of becoming excited in a way which got him into trouble on some previous occasion and his symptoms of fear may be a partial although unrecognised memory of this experience.

CASE 1.—A territorial soldier aged 26, who had served satisfactorily for 15 months in an anti-aircraft battery since the outbreak of war, became afraid that he would show fear by trembling. He knew that his officer was thinking of recommending him for a commission. He went sick. During treatment it became apparent that he was frightened of becoming overwhelmed by outbursts of enthusiastic kindly thoughts about the enemy. In the past he had often influenced people who had tended to frustrate him by becoming ingratiating, and by exploiting a well-developed capacity for being enthusiastically pleasant. Tremor was the 'fear signal." It was a partial memory of trembling with happy excitement. He had good reason to believe that the wish to ingratiate the enemy would lead to difficulties similar to, or greater than, those he had experienced in the past when his enthusiasm had not proved as acceptable as he had hoped.

A patient may be frightened of unconscious wishes to grieve.

CASE 2.—A soldier of the last war, now aged 45, who fought successfully through a recent campaign except for 4 hours' unconsciousness after a bomb-burst nearby. Some time after returning to this country he became generally frightened, especially concerning his sight, which he said was failing. During treatment he discovered a wish to cry about a situation which was developing at home. His wife had begun to work and he thought she was neglecting their children. Before treatment he had only felt annoyed at his wife's behaviour. His fear and difficulty with vision had begun when he had for the first time, nearly cried while writing to his wife. His sorrow was connected not only with his neglected children but also with memories of being neglected in childhood and with feelings that he had been neglected in his unit.

A patient may be frightened of his unconscious rage.

CASE 3.—A man of 23 who had stammered at times throughout his life was annoyed when not called up into the corps for which he considered himself most suited. He became ill at

TREATMENT OF BURNS IN SWITZERLAND

TANNING methods in the treatment of burns receive enthusiastic support from Major Henschen of the University Clinic at Basle (*Helv med Acta*, April, 1941 p 77) It may well be that the tragic after results of this treatment in the deeper degrees of burning have not come to his notice but it comes as rather a shock to find that it is precisely in those degrees of burn in which the use of tannic acid is in this country regarded with so much misgiving that he most strongly advises it Henschen follows Dupuytren's historic classification of burns into six degrees For the first two—erythema and blistering—he considers tanning methods pointless Even in third-degree burns he would restrict its use to cases in which, over a large burnt area, there are only apparent a few scattered islands of epithelium In the fourth degree, however, he believes he has the main indication for tanning Here all the epithelium is destroyed, and British plastic surgeons might be expected to shudder at the very mention of the formation of a tannic scar on the deep tissues In two other directions Henschen is in more direct agreement with us He advocates the prophylactic use of sulphonamide drugs in the prevention of septicæmia in burns, and he believes in early skin-grafting to prevent contracture of scars and consequent crippling and deformity He suggests the local treatment of burns by the application of 5–15 g of sulphonamide powder, mixed with some form of anæsthetic powder to lessen the pain it might produce, but does not mention any personal experience of the effects The clean granulating wound he skin-grafts, believing that the graft has a direct stimulating effect on the deep healing of the wound He evidently prefers the Thiersch graft where the area to be covered is not too extensive, because, as he puts it, the thinner the graft the greater its vitality For larger wounds he uses a thicker graft, which is intermediate between the thin Thiersch and the deeper Wolfe graft He stretches the graft out on a towel rung out in saline solution and converts it into a type of " sieve " graft with multiple incisions In this way he allows discharge from the granulating area to escape through the graft and finds that the graft itself can more easily be stretched to the size and shape of the area to be covered

Births, Marriages and Deaths

BIRTHS

BARWELL—On Aug 16 at Woking the wife of Surgeon Lieutenant T E Barwell R N V R —a daughter

BEDFORD—On Aug 21 at Aldershot the wife of Lieut Colonel Evan Bedford R A M C —a son

THE SOLDIER'S DEFENCE AND THE PUBLIC'S ATTITUDE*

W CLIFFORD M SCOTT, M D Toronto
PHYSICIAN TO THE LONDON CLINIC OF PSYCHO ANALYSIS,
PSYCHIATRIC SPECIALIST, E.M.S

THE soldier's commonest single defence against more serious psychiatric illness is a complaint that he is afraid of some aspect of the situation which war has brought about Common variations of this complaint are that he is afraid of becoming ill or that he is already ill The public accepts physical illness, injury and abnormal fear as understandable war casualties Fear of a situation which is frequently described as horrible or intolerable is now an acceptable type of war casualty. This is due to a change in the public's attitude during the past generation

Before the last war the valorous soldier was considered to be fearless To fear that the enemy was too dangerous to attack was cowardice and to show it might turn his superior officers into assailants more dangerous than the enemy Some soldiers were shot Owing perhaps to the size of the conscript armies of the last war the problem of fear was forced on the military physician Gradually the belief that war stimulated instincts—among them a self-preservative instinct—became common It was accepted that thwarting this instinct led invariably to a fear reaction, even though in some people this reaction might be slight The problem of treatment became a problem of keeping this fear reaction within such normal bounds that there was no interference with social duty The stimulus to the self-preservative instinct was considered to be the likelihood of death This widely accepted psychopathology was discussed both inside and outside the medical profession and was found among those who gave evidence before the War Office committee of inquiry into shell shock, which reported in 1922

Since the last war two lines of research have produced a wide gulf separating the attitude of the general public and the general medical world from that of many psychiatrists This gulf is as wide in many ways as that present during the early years of the last war when shell-shock was still only a neurological problem and cowardice only a crime The first type of research consisted of behaviouristic studies of infants in an attempt to identify the nature and development of early fear reactions, and the second of psycho-analytic studies into the relation of the symptoms of fear to previous emotional states Observation of infant development, both by those neurologically and those psychologically oriented, has not provided evidence that there is a primary pattern of fear reaction in infancy No single fear reaction can be identified in infancy which contains within it all or most of the signs and symptoms of fear reactions in later life Studies of the startle reaction have led to the conclusion that there may be a short reflex phase followed by a variety of secondary reactions The early aspects of what may later become fainting reactions and stupor reactions have been found to be quite complex from the time they can be identified Perhaps the safest conclusion to be drawn from the behaviouristic studies is that evidence of primary satisfaction and primary rage are the only easily identified primary reactions Fear and sorrow reactions appear even at their onset to be more complicated and derivative than was previously held

Psycho-analytic studies have developed rapidly, especially since the publication by Freud in 1926 of his book "Inhibition, Symptom and Anxiety" Work in this country, especially with children and the mild psychotic reactions in adults, has clarified some of the problems involved Freud related the symptoms of fear to symptoms of other types and to previous traumata By trauma he meant a situation producing pain or frustration of instinctual need He showed that the theoretical basis of anxiety neurosis as formulated by him in 1895 was largely superseded. His newer conception was that fear was a signal—which sometimes could be considered abnormal and sometimes normal—meaning that something had to be done or worse would ensue The content of the signal (the symptoms of the fear) was a partial memory of a state which had been present during a previous trauma This formulation led to an increase in our knowledge of the way the ego developed under the influence of fear, and to a more detailed understanding of types of neurotic and psychotic fear But the older conception, that repression of instinctive activity leads to transformation of the repressed instinctual energy into something appearing in consciousness as fear, is still too commonly used in treatment The widespread neglect of the work done in the past fifteen years must be, in itself, an attempt to deny the complexity of what goes on unconsciously In looking back it is difficult to understand why signal fear was so long unformulated Such expressions as "I was afraid I'd laugh," "I was afraid I'd cry," "I was afraid I'd lose my temper," "I was afraid he'd know I was afraid," "I was afraid I'd frighten him" show that few doubt that one can be frightened consciously of one's own impulses These situations are expressed even more openly in such phrases as "I wanted to laugh but I was afraid to," "I wanted to cry but I was afraid to" That one could be frightened of one's unconscious impulses remained for long undiscovered; the more unconscious the content of the fear the more likely are we to use the word anxiety instead of fear in describing it Perhaps there are many psychopathological truths hidden behind current idioms which are as yet neither utilised nor consciously understood

THREE EXAMPLES OF FEAR

If common sayings mentioning fear express an unconscious instead of a conscious content they disclose widely different psychopathological problems When a patient says he is afraid, he may be unconsciously on the verge of becoming excited in a way which got him into trouble on some previous occasion and his symptoms of fear may be a partial although unrecognised memory of this experience

CASE 1 —A territorial soldier aged 26, who had served satisfactorily for 15 months in an anti aircraft battery since the outbreak of war, became afraid that he would show fear by trembling He knew that his officer was thinking of recommending him for a commission. He went sick. During treatment it became apparent that he was frightened of becoming overwhelmed by outbursts of enthusiastic kindly thoughts about the enemy In the past he had often influenced people who had tended to frustrate him by becoming ingratiating, and by exploiting a well-developed capacity for being enthusiastically pleasant Tremor was the "fear signal" It was a partial memory of trembling with happy excitement He had good reason to believe that the wish to ingratiate the enemy would lead to difficulties similar to, or greater than, those he had experienced in the past when his enthusiasm had not proved as acceptable as he had hoped.

A patient may be frightened of unconscious wishes to grieve

CASE 2 —A soldier of the last war, now aged 45, who fought successfully through a recent campaign except for 4 hours' unconsciousness after a bomb-burst nearby Some time after returning to this country he became generally frightened, especially concerning his sight, which he said was failing During treatment he discovered a wish to cry about a situation which was developing at home His wife had begun to work and he thought she was neglecting their children Before treatment he had only felt annoyed at his wife's behaviour His fear and difficulty with vision had begun when he had, for the first time, nearly cried while writing to his wife His sorrow was connected not only with his neglected children but also with memories of being neglected in childhood and with feelings that he had been neglected in his unit

A patient may be frightened of his unconscious rage

CASE 3 —A man of 23 who had stammered at times throughout his life was annoyed when not called up into the corps for which he considered himself most suited He became ill at ease, easily frightened and stammered more. Under treatment he said he would soon be fit. He said he had conquered his trouble before and would again. Change was slow until after an air raid, during which he became very angry at the Germans. He had difficulty in talking of the content of his anger. He said he was frightened of his thoughts. He looked happy and excited and wanted to go back to duty. During a few days' treatment he became calmer and the content changed. At first he wanted all Germans killed, later he wanted them all castrated, still later he wanted birth control measures enforced throughout Germany, finally he discussed prolonged re education of the enemy after victory. There was a close connexion between the degree of his fear and the primitive nature of his rage: the more primitive his rage the greater was his fear.

---

* Read at a meeting of the medical section of the British Psychological Society at Nottingham on April 19

Such instances could be multiplied but those quoted show similarities between the symptoms of conscious fear and the partial, and at first unrecognised, memory of an emotion which caused trouble when expressed at an earlier age. A similar emotion is being evoked again by some aspect of the patient's general situation in war at the moment he becomes frightened. Quite possibly many of the same mechanisms are at work in patients who do not become abnormally frightened until they are tested in the greater test of face to face mortal combat.

THE CHANGING VIEW OF FEAR

The gradual change in the public's attitude to fear during the last war no doubt made it possible to do as much as was done for those showing abnormal fear at that time. The change in attitude came about mostly through education in the Services and among civilians, most likely through reading and conversation. Now that it is easier to ascertain the amount and nature of unconscious fear, sorrow, love or hate related to complaints of physical illness or fear, many of those suffering from mild degrees of fear might be helped simply by a more widespread public acceptance of the psychopathological facts I have mentioned. The milder forms of fear, expressed in social conversation or to the family physician, might be lessened by general education. The more severe forms of fear which bring patients to hospital might be more easily treated if there was another advance in public understanding as great as that which occurred during the last war.

If the unconscious emotions which, when strong, may be signalled consciously by fear were more frequently mentioned at the cinema, by the press and wireless, in churches, and in such public pageantry as persists, mourning might be completed rather than postponed, tolerance of grief might be increased, and hate and love might become less frightening. The pleasures of hating might be more easily accepted without the accompanying fear that all enjoyment would be disturbed by having been once connected with hating. The fear that once having hated a person you can find nothing left in him to love might be partly overcome. An impulse towards appeasement may well be tolerated and postponed rather than denied. It is denial of such impulses, rather than their conscious toleration, which is dangerous, for the repressed impulse may return with full force and jeopardise a man's life and his country's safety. To wish to appease an enemy during war is a different thing from being prepared to meet him on friendly terms later for the purpose of convincing him that a good relationship with him is possible. The idea of tolerating and postponing kindly wishes till after the destructive wishes of the enemy have been overcome might thus become general and acceptable. With the development of a cultural attitude along these lines it would become easier to reassure patients and to make them understand that problems similar to theirs were widespread throughout the community. The patients themselves would be helped by the knowledge that they were tackling in private problems which their rulers were tackling in public. The courage to "take it"—to put up with the burden of being sinned against—could well be expanded to include the courage to "bear up"—to put up with desire to grieve for one's friend or foe, with desire to love one's assailant and with desire to fight him with primitive rage—and at the same time to take a share in the duties of a community at war.

RENAL COMPLICATIONS OF SULPHAPYRIDINE THERAPY

SYDNEY M. LAIRD,
M.D., B.SC. GLASG., F.R.F.P.S., D.P.H.
MAJOR, R.A.M.C.

THE toxic manifestations arising during sulphonamide therapy are in general common to all members of the group, but certain of these drugs may give rise to signs of intolerance or toxicity which are peculiar to themselves—for example, the sulphanilyl-sulphanilamide series, of which Uleron is representative, may produce peripheral neuritis. In the past two years hæmaturia has been reported as developing during or after the use of sulphapyridine, and more recently the closely allied sulphathiazole series of drugs have been similarly incriminated.[35 18] Earlier reports[26 19 14 5] suggested that the hæmaturia produced by sulphapyridine was mechanical rather than toxic in origin and did not constitute a serious complication, but when Southworth and Cooke[43] reported that it was in some cases associated with abdominal pain and nitrogen retention, and when Tsao and others[47] reported a fatal case of anuria, the potential seriousness of the hæmaturia was more fully appreciated.

CASE-REPORTS

Since the introduction of intensive dosage, the complication had been more common, and I am here reporting five cases arising in soldiers under treatment for gonorrhœa between December, 1940, and March, 1941.

CASE 1.—A healthy soldier, aged 22, was admitted to hospital on Dec. 16, 1940, suffering from acute gonococcal urethritis. No history of scarlet fever or nephritis. He had received no treatment for his urethritis, which had developed on Dec. 5. Sulphapyridine, 1 g. four hourly, was begun immediately, the daily fluid intake being about 2000 c.cm. In the early hours of the morning of Dec. 18, after a total of 12 g. sulphapyridine, he developed severe pain in the lumbar region accompanied by pain on micturition. Pyrexia (99° F.), headache and retching without vomiting were also present. Gross hæmaturia was noted and the right kidney was found to be palpable and tender. Urinary findings were sp. gr. 1014, acid, thick cloud of albumin, deposit showed very numerous red cells and many fine needle shaped crystals of acetyl sulphapyridine. The bowels were regular, the tongue being only slightly furred. Sulphapyridine was immediately stopped and fluids by mouth pressed. A kaolin poultice was applied over the lumbar region and morphia and atropine were required to keep the patient comfortable. The pain was less severe next day and had abated completely by Dec. 20. On this date the urine was normal on macroscopic examination and on the 21st only a few red cells were seen microscopically. The patient made a rapid recovery and was discharged from hospital on the 23rd with a normal urine and without clinical evidence of urethritis. Thereafter he was seen as an outpatient, and, on his last visit on March 5, 1941, the urine was normal and direct radiography of the renal tract revealed no abnormality.

CASE 2.—A healthy soldier, aged 24, was admitted to hospital on Jan. 8, 1941, suffering from acute gonococcal urethritis. No history of scarlet fever or nephritis. He had received no treatment for the urethritis. Sulphapyridine, 1 g. four hourly, was begun immediately, the daily fluid intake being about 2000 c.cm. Shortly before midnight on Jan. 9, after a total of 9 g. sulphapyridine, he developed pain in the abdomen which was worse on the right side and on occasion passed down into the right groin and testicle. He complained of nausea during that day, and next day of headache, vertigo and vomiting. The bowels were open daily. On the morning of the 10th gross hæmaturia was noted and the right kidney was palpable and tender. At this stage a total of 12 g. of sulphapyridine had been administered and the drug was now stopped. Fluids were given by mouth at the rate of one pint an hour and an enema was given. No sedatives were required as the pain was not very severe. The abdominal pain had abated by the 12th, on which day a mild sulphapyridine rash of the morbilliform type appeared. The urine had returned to normal by the 13th. The patient was discharged from hospital on the 18th with no clinical evidence of urethritis and free from symptoms.

Urinary findings—Jan 10 abundant red blood corpuscles and a moderately large number of crystals of acetyl sulphapyridine Jan 11 moderate number of red blood corpuscles, no crystals seen Jan 13 sp gr 1005, reaction neutral, no albumin, normal on microscopic examination

CASE 3—A previously healthy soldier, aged 26, was admitted to hospital on Jan 20, 1941, suffering from acute gonococcal urethritis No history of scarlet fever or nephritis He had received no treatment for the urethritis Sulphapyridine, 1 g four-hourly, was begun immediately, the daily fluid intake being about 2000 c cm At 6 A.M on Jan 22, after 11 g of sulphapyridine had been administered, bilateral pain of renal distribution was experienced, and half an hour later hæmaturia was noticed for the first time The bowels were open regularly Sulphapyridine was stopped after a total of 12 g had been administered On the 23rd the pain had become more severe and tenderness over both kidneys were noted. Fluids were pressed, morphia and atropine were given and measurement of the urinary output was begun At 9 30 A.M on the 24th pain and tenderness were less but were still present, vomiting was persistent and pyrexia (99° F) was noted The little urine passed during the previous night contained less blood than on former occasions At 7 P M anuria had been present for just over 12 hours, vomiting continued and there was evidence of dehydration and nitrogen retention (blood-urea at 2 P M 61 mg per 100 c cm) The bladder was empty and pain and tenderness were more definite over the right kidney A direct radiogram of the renal tract revealed no abnormality Cystoscopy performed under local anæsthesia at 9 15 P M showed no urine in bladder, bladder mucosa injected and covered with shreds of mucus, right ureteric orifice injected, left œdematous with raised edges The right ureter was catheterised and, while this was being done a small blood clot was dislodged from the ureteric orifice Thereafter the catheter passed easily to the renal pelvis Sterile saline, 3 c cm, was injected and immediately a thick, brown sludge began to flow from the catheter this substance did not clot The catheter was left in situ and just over 10 oz was drained off while 2½ pints of saline glucose drip was given intravenously A rigor developed during the administration of the third pint The patient remarked that his pain abated suddenly and this coincided with the establishment of drainage through the ureteric catheter After operation the patient was free from discomfort and maintained a satisfactory fluid intake and urinary output The temperature returned to normal on Jan 28, and on the 30th the blood-urea was 36 mg per 100 c cm The urine improved steadily and had returned to normal by Feb 1 On the 3rd contrast radiography of the renal tract revealed normal function and appearance and the patient was discharged on the 6th, free from all symptoms

Urinary findings—Jan 23 very abundant red blood corpuscles, no crystals seen Jan 24 (9 30 A M) sp gr 1012, acid, albumin — — —, red blood corpuscles + — —, no crystals seen. Jan 24 (catheter specimen from right ureter) strongly acid, deposit showed much blood and a large proportion of very small clots, fair number of ureteric epithelial cells, few fragments of pelvic epithelium and one or two blood casts, no unusual crystals seen Jan 27 sp gr 1014, acid, albumin +, red blood corpuscles — + Jan. 28 sp gr 1011, acid, albumin —, moderate number of red blood corpuscles, no casts Jan. 29 sp gr. 1012, acid, albumin —, red blood corpuscles — +, no casts Jan. 30 sp gr 1009, slightly acid, trace of albumin, moderate number of red blood corpuscles and pus cells Feb 1 sp gr 1007, neutral, no albumin, very few red blood corpuscles and pus cells

Urine output—Jan. 24 12 30 A.M, 45 c cm, 6 20 A M, 60 c cm, (8 P M cystoscopy) 8 30 P M. to midnight, over 300 c cm, Jan 25 2310 c cm Jan. 26 2820 c cm.

CASE 4—A previously healthy soldier, aged 30, undergoing treatment for gonococcal urethritis He was originally admitted to hospital on Feb 11 and received 6 g of sulphapyridine daily for four days The urethral condition subsequently recurred and he was readmitted for further treatment The first course of sulphapyridine caused headache, vertigo, nausea and vomiting, but there was no evidence of renal irritation A second course was begun on Feb 25 and this again resulted in headache, vertigo, nausea and vomiting The vomiting led to the fluid intake becoming lower than was desired and when pain developed in the left hypochondrium on the 28th the drug was stopped after a total of 18 g sulphapyridine had been administered Naked eye examination of the urine revealed no obvious abnormality until March 2, when it looked smoky, sp gr 1018, acid, albumin — —, red blood corpuscles — — — —, no acetyl sulphapyridine crystals seen Fluids were pressed as much as possible by mouth, and by March 4 the pain had abated and the urine was microscopically normal apart from an occasional red blood corpuscle A third course of chemotherapy was begun on March 8, because the urethral condition was still unsatisfactory Pyrexia, nausea vomiting, pain in the right lumbar region and hæmaturia reappeared on the 10th after 11 g of sulphapyridine had been administered Stopping the drug and pressing fluids by mouth led to the rapid abatement of these symptoms

Urinary findings—March 10 cloudy but no macroscopic blood, pH 7 6, red blood corpuscles — — large number of acetyl sulphapyridine crystals March 11 sp gr 1008 neutral trace of albumin, occasional red blood corpuscles, no crystals seen March 12 normal

CASE 5—A previously healthy soldier, aged 31 admitted to hospital on March 4, 1941, suffering from acute urethritis He was given 6 g sulphapyridine daily and a fluid intake of 7 pints a day was advised On the 6th after 12 g of sulphapyridine, he developed gross macroscopic hæmaturia and pain in the region of the right kidney Direct radiography of the renal tract revealed no abnormality The drug was stopped at once and a pint of water was given by mouth every hour The patient admitted that he had not previously carried out his instructions with regard to fluid intake A rapid diuresis was effected and a dramatic abatement of the renal irritation resulted

Urinary findings—March 3 10 A.M sp gr 1020 pH 6 4 red blood corpuscles and acetyl-sulphapyridine crystals — — + — — — At 1 P M sp gr 1005, pH 6 8, red blood corpuscles and crystals — — — At 2 P M sp gr 1001, pH 7 0, no red blood corpuscles or crystals seen

It will be noted that the daily fluid intake in all these cases of hæmaturia was below 3000 c cm The importance of the fluid intake in relation to renal irritation is well illustrated by the table which presents the relevant data in a series of adult male patients who have been treated solely under my care for urethritis

RELATION OF HÆMATURIA TO FLUID INTAKE

Cases	Sulphapyridine daily (g)	Fluid intake (c cm daily)	Cases of hæmaturia
162	3 g	Over 3000	0
323	4 g	Over 3000	0
104	4 g	2000	1
140	6 g	2000	4
65	6 g	Over 3000	0

CLINICAL PICTURE

The clinical picture produced by these renal complications may take one of three forms In the first hæmaturia is only detected microscopically and pain is sometimes present in the second the hæmaturia is gross, usually accompanied by pain but clears up rapidly on withdrawing the drug and giving ample fluids, and, in the third, despite such remedial measures, there is impairment of renal function which may lead to nitrogen retention anuria and death These forms may appear as separate entities but they may, in fact, only constitute progressive stages of the same process

Examples of the mildest form will be detected only by frequent microscopic examination of the urine, and hence reports of its occurrence depend partly on the thoroughness of investigation. McCann[30] reported that routine microscopical examination revealed red cells in the urine of 29 out of 65 male patients receiving sulphapyridine for gonorrhœa · Nissen and Roesgaard[33] found microscopic hæmaturia in 10 out of 41 cases of pneumonia treated with sulphapyridine Hegglin[21] reported severe hæmaturia in 1% of cases but stated that minor degrees were more common, Flippin[13] found microscopic hæmaturia in 5% and gross hæmaturia in 1% of patients receiving sulphapyridine Long and others[25] reports that 8% of 297 cases treated with sulphapyridine developed hæmaturia The pain is usually ill-defined and may especially in pneumonia be mistaken for a manifestation of the disease under treatment If the drug is withdrawn and ample fluids given before the condition has progressed to the second stage red cells disappear from the urine within a few days, though they will probably reappear if further sulphapyridine is given

In the absence of frequent routine microscopic examinations of the urine renal complications will only be detected when they have progressed to the second stage The onset of this degree of hæmaturia is often associated with severe pain, usually confined to the lumbar region but sometimes indistinguishable from the typical distribution of renal and ureteric colic At first the pain may be confined to one flank, but soon may become bilateral, and it is commonly associated with malaise vomiting and pyrexia Tenderness may be elicited over the kidney and bladder and, more rarely, over the line of the ureter The reported cases show that, in adults, the second stage is reached 48–96 hours after the commencement of chemotherapy, when between 12 and 24 g of sulphapyridine has been taken, and that patients developing this complication are receiving at least 5 g a day In adolescents and infants when dosage has been unusually heavy, symptoms have arisen in less than 48 hours[5, 42] Prompt recognition of this stage and immediate treatment will often lead to a dramatic abatement of macroscopic hæmaturia This is well illustrated by case 5, where the urine became free from blood on naked-eye examination three hours after remedial measures were begun Sulphapyridine should be stopped, the urinary output measured, and fluids given at the rate of a pint an hour When there is severe vomiting, saline and 5% glucose should be given rapidly by the continuous intravenous drip method Failure to produce diuresis within twelve hours indicates that the condition has progressed to the third stage

The third stage is characterised by a diminished output of grossly blood-stained urine and may progress to complete anuria Coincident with this there is increasing nitrogen retention which, if unrelieved, may lead to death Œdema and hypertension seem to be rare but have been described in one case by Kilgour[24]

ÆTIOLOGY

When sulphapyridine is absorbed into the blood, part of it is acetylated, and hence the kidney is called on to excrete acetyl-sulphapyridine in addition to unconjugated or free sulphapyridine There is considerable variation between individual patients in the proportion undergoing acetylation and the acetyl-sulphapyridine is much less soluble than the unconjugated form, particularly in an acid medium As the glomerular filtrate passes through the tubular system of the kidneys, the urine becomes increasingly acid and undergoes considerable concentration This process, in association with intensive dosage of sulphapyridine, an unusually high degree of acetylation, a low fluid intake or an abnormal fluid loss, will favour the precipitation of crystals of acetyl-sulphapyridine These crystals are sharp and may form a nidus for the formation of small calculi which produce mechanical irritation of the renal pelvis and ureter Such trauma causes hæmaturia, œdema, and possibly reflex spasm, which, by producing ureteric obstruction, lead to hydronephrosis, anuria and nitrogen retention

The production of crystals depends on several factors intensity of dosage , rate of absorption and excretion , the proportions of free and conjugated sulphapyridine in the blood and urine , the amount of fluid intake and loss , and the concentration of the urine * While most of these factors are extrinsic and amenable to control by the physician, others are intrinsic and depend on the personal idiosyncrasy of the patient

TREATMENT AND PROPHYLAXIS

The principle underlying the treatment of any degree of hæmaturia due to sulphapyridine is the rapid elimination of the drug from the body To effect this, administration of the drug should be stopped forthwith and measurement of the urinary output instituted Where the output is subnormal, blood-urea estimations should be carried out Fluid intake must be forced up to a high level, using the intravenous route if vomiting is present or the patient is unconscious or uncooperative from any other cause A solution of 5% dextrose in saline, or 4 28% sodium sulphate with 10% glucose in normal saline, is commonly used for intravenous medication, and the total of fluids administered in 24 hours should be at least 3000 c cm Morphia and atropine may be required to relieve pain, and other general measures of benefit include rest in bed, the application of a kaolin poultice to the lumbar region, and the evacuation of the lower bowel by enemata These measures are indicated in the first and second stages of the complication, although in exceptional cases, where withdrawal of the drug may endanger the patient's life, continuation of chemotherapy may be justified If so the urinary output and blood-urea must be carefully observed so that the onset of stage three is recognised immediately

When the fluid intake is satisfactory, increasing oliguria means that the complication has advanced to the third stage The patient may still respond to the regime outlined for stages 1 and 2, but the development of anuria is the signal for active surgical intervention in order to relieve the mechanical obstruction of the urinary tract and repeated lavage of the ureter and renal pelvis with saline or distilled water is the treatment of choice The lavage fluid should be at body temperature as this facilitates solution of the crystals This procedure, suggested by Tsao and others,[47] apparently proved a life-saving measure in my case 3 The operation can be performed under local anæsthesia and without detriment to the patient, who would otherwise be regarded as a poor operative risk It is preferable to decapsulation of the kidneys, pyelotomy and retrograde catheterisation, although this operation may prove successful in cases where direct ureteric catheterisation is prevented by technical difficulties[41] Operation should be carried out within twelve hours of the onset of anuria to avoid damage to the kidneys from pressure indeed, Smith and others[41] advise that the forcing of fluids should not be continued once renal function is obviously impaired, in view of the hydronephrosis which has been found in such cases both at open operation and autopsy With the re-establishment of urinary secretion, however, an adequate fluid intake should once again be maintained The ureteric catheter or catheters should be allowed to remain in situ after the patient has returned to the ward and until the output of urine has reached a satisfactory level

Cystoscopy may reveal that urinary secretion has ceased from both ureters and it is then necessary to decide whether unilateral or bilateral catheterisation is required Evidence on this point is scanty Carroll, Shea and Pike,[9] Sadusk, Waters and Wilson,[40] and Plummer and McLellan[36] catheterised both ureters in their cases but in case 3 only the right ureter was catheterised, and although no serious obstruction was met as soon as drainage from the right renal pelvis was established, pain was relieved and secretion from the left ureter took place This observation suggests that the ureteric obstruction may partly depend on reflex spasm of the ureteric wall Thus while bilateral catheterisation is advocated as a routine in these cases if technical difficulties arise, it may be borne in mind that catheterisation of one ureter has been successful in re-establishing secretion of urine from both kidneys

The prevention of significant hæmaturia during sulphapyridine therapy depends essentially on maintaining a fluid intake of at least 3000 c cm and a urinary output of 1500 c cm in 24 hours This is of especial importance when the dosage exceeds 5 g a day, a threshold above which this complication is most often encountered The concurrent administration of alkalis with sulphapyridine has been advocated by Marshall,[33] Backhouse[5] and THE LANCET (1939, 2, 893), but it has since been demonstrated that acetyl-sulphapyridine may crystallise out in alkaline urine[46, 47, 8, 40, 41] Haviland and Britton[20] have shown that the solubility of acetyl-sulphapyridine in urine remains essentially the same for a range of pH 3 3 to 7 4 and that the solubility at pH 7 9 is not therapeutically significant When intensive dosage is employed, it is advisable that the urine should be examined microscopically each day so that signs of renal irritation will be detected in the first stage, in which treatment is invariably successful Similar examination is called for in any patient who complains

---

* Shortage of space has made it impossible to set out the experimental, biochemical and post mortem evidence on which this summary of the ætiology is based

has progressed to the second stage red cells disappear from the urine within a few days, though they will probably reappear if further sulphapyridine is given.

In the absence of frequent routine microscopic examinations of the urine renal complications will only be detected when they have progressed to the second stage. The onset of this degree of hæmaturia is often associated with severe pain, usually confined to the lumbar region but sometimes indistinguishable from the typical distribution of renal and ureteric colic. At first the pain may be confined to one flank, but soon may become bilateral, and it is commonly associated with malaise, vomiting and pyrexia. Tenderness may be elicited over the kidney and bladder and, more rarely, over the line of the ureter. The reported cases show that, in adults, the second stage is reached 48–96 hours after the commencement of chemotherapy, when between 12 and 24 g. of sulphapyridine has been taken, and that patients developing this complication are receiving at least 5 g. a day. In adolescents and infants when dosage has been unusually heavy, symptoms have arisen in less than 48 hours.[5, 42] Prompt recognition of this stage and immediate treatment will often lead to a dramatic abatement of macroscopic hæmaturia. This is well illustrated by case 5, where the urine became free from blood on naked-eye examination three hours after remedial measures were begun. Sulphapyridine should be stopped, the urinary output measured, and fluids given at the rate of a pint an hour. When there is severe vomiting, saline and 5% glucose should be given rapidly by the continuous intravenous drip method. Failure to produce diuresis within twelve hours indicates that the condition has progressed to the third stage.

The third stage is characterised by a diminished output of grossly blood-stained urine and may progress to complete anuria. Coincident with this there is increasing nitrogen retention which, if unrelieved, may lead to death. Œdema and hypertension seem to be rare but have been described in one case by Kilgour.[24]

ÆTIOLOGY

When sulphapyridine is absorbed into the blood, part of it is acetylated, and hence the kidney is called on to excrete acetyl-sulphapyridine in addition to unconjugated or free sulphapyridine. There is considerable variation between individual patients in the proportion undergoing acetylation and the acetyl-sulphapyridine is much less soluble than the unconjugated form, particularly in an acid medium. As the glomerular filtrate passes through the tubular system of the kidneys, the urine becomes increasingly acid and undergoes considerable concentration. This process, in association with intensive dosage of sulphapyridine, an unusually high degree of acetylation, a low fluid intake or an abnormal fluid loss, will favour the precipitation of crystals of acetyl-sulphapyridine. These crystals are sharp and may form a nidus for the formation of small calculi which produce mechanical irritation of the renal pelvis and ureter. Such trauma causes hæmaturia, œdema, and possibly reflex spasm, which, by producing ureteric obstruction, lead to hydronephrosis, anuria and nitrogen retention.

The production of crystals depends on several factors: intensity of dosage; rate of absorption and excretion; the proportions of free and conjugated sulphapyridine in the blood and urine; the amount of fluid intake and loss; and the concentration of the urine.[*] While most of these factors are extrinsic and amenable to control by the physician, others are intrinsic and depend on the personal idiosyncrasy of the patient.

TREATMENT AND PROPHYLAXIS

The principle underlying the treatment of any degree of hæmaturia due to sulphapyridine is the rapid elimination of the drug from the body. To effect this, administration of the drug should be stopped forthwith and measurement of the urinary output instituted. Where the output is subnormal, blood-urea estimations should be carried out. Fluid intake must be forced up to a high level, using the intravenous route if vomiting is present or the patient is unconscious or uncooperative from any other cause. A solution of 5% dextrose saline, or 4.28% sodium sulphate with 10% glucose normal saline, is commonly used for intravenous medication, and the total of fluids administered in 24 hours should be at least 3000 c.cm. Morphia and atropine may be required to relieve pain, and other general measures of benefit include rest in bed, the application of a kaolin poultice to the lumbar region, and the evacuation of the lower bowel by enemata. These measures are indicated in the first and second stages of the complication, although in exceptional cases, where withdrawal of the drug may endanger the patient's life, continuation of chemotherapy may be justified. If so the urinary output and blood-urea must be carefully observed so that the onset of stage three is recognised immediately.

When the fluid intake is satisfactory, increasing oliguria means that the complication has advanced to the third stage. The patient may still respond to the regime outlined for stages 1 and 2, but the development of anuria is the signal for active surgical intervention in order to relieve the mechanical obstruction of the urinary tract and repeated lavage of the ureter and renal pelvis with saline or distilled water is the treatment of choice. The lavage fluid should be at body temperature as this facilitates solution of the crystals. This procedure, suggested by Tsao and others,[47] apparently proved a life-saving measure in my case 3. The operation can be performed under local anæsthesia and without detriment to the patient, who would otherwise be regarded as a poor operative risk. It is preferable to decapsulation of the kidneys, pyelotomy and retrograde catheterisation, although this operation may prove successful in cases where direct ureteric catheterisation is prevented by technical difficulties.[41] Operation should be carried out within twelve hours of the onset of anuria to avoid damage to the kidneys from pressure; indeed, Smith and others[41] advise that the forcing of fluids should not be continued once renal function is obviously impaired, in view of the hydronephrosis which has been found in such cases both at open operation and autopsy. With the re-establishment of urinary secretion, however, an adequate fluid intake should once again be maintained. The ureteric catheter or catheters should be allowed to remain in situ after the patient has returned to the ward and until the output of urine has reached a satisfactory level.

Cystoscopy may reveal that urinary secretion has ceased from both ureters and it is then necessary to decide whether unilateral or bilateral catheterisation is required. Evidence on this point is scanty. Carroll, Shea and Pike,[9] Sadusk, Waters and Wilson,[40] and Plummer and McLellan[36] catheterised both ureters in their cases but in case 3 only the right ureter was catheterised, and although no serious obstruction was met as soon as drainage from the right renal pelvis was established, pain was relieved and secretion from the left ureter took place. This observation suggests that the ureteric obstruction may partly depend on reflex spasm of the ureteric wall. Thus while bilateral catheterisation is advocated as a routine in these cases if technical difficulties arise, it may be borne in mind that catheterisation of one ureter has been successful in re-establishing secretion of urine from both kidneys.

The prevention of significant hæmaturia during sulphapyridine therapy depends essentially on maintaining a fluid intake of at least 3000 c.cm. and a urinary output of 1500 c.cm. in 24 hours. This is of especial importance when the dosage exceeds 5 g. a day, a threshold above which this complication is most often encountered. The concurrent administration of alkalis with sulphapyridine has been advocated by Marshall,[32] Backhouse[5] and THE LANCET (1939, 2, 893), but it has since been demonstrated that acetyl-sulphapyridine may crystallise out in alkaline urine.[46, 47, 8, 40, 41] Haviland and Bratton[20] have shown that the solubility of acetyl-sulphapyridine in urine remains essentially the same for a range of pH 3.3 to 7.4 and that the solubility at pH 7.9 is not therapeutically significant. When intensive dosage is employed, it is advisable that the urine should be examined microscopically each day so that signs of renal irritation will be detected in the first stage, in which treatment is invariably successful. Similar examination is called for in any patient who complains these failures were due to a high lesser-curve lesion, which either by its size or by the distortion it caused presented an insuperable obstruction to the passage of the instrument No amount of manipulation of the proximal end could alter the lateral position of the flaccid distal part, and, since force could only result in dangerous trauma, there was no alternative to the abandonment of the examination in these circumstances With the new instrument however, the end can simply be lifted clear of the obstruction and guided safely onwards *under vision* into the cavity of the stomach, when the inspection can be completed

---

[*] Shortage of space has made it impossible to set out the experimental, biochemical and post mortem evidence on which this summary of the ætiology is based.

Secondly, the lateral mobility of the objective permits a much more detailed examination of the mucosa to be made by approaching or withdrawing from any particular area at will The mucosal surface is always in focus and the degree of magnification of any part can be controlled by adjusting its distance from the objective Thus, a near view of the pylorus can now be obtained More proximally, the objective can stand back from the posterior wall to provide a more comprehensive view of it than can be obtained by the close approximation at which the passively flexible instrument naturally lies The latter limitation of the Wolf-Schindler instrument was well recognised and the inflatable retracting balloon was designed to overcome this by pushing away the mucosa from too close contact with the objective Although the method was effective, the balloon was in practice easily damaged and its external rubber capillary tube caused some discomfort to the patient It has now been found superfluous, since retroflexion of the distal end of the new instrument produces the same effect with greater range of movement

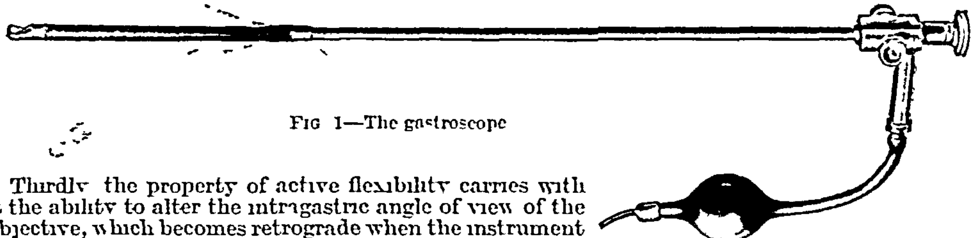

FIG 1—The gastroscope

Thirdly the property of active flexibility carries with it the ability to alter the intragastric angle of view of the objective, which becomes retrograde when the instrument is curled forwards and prograde when it is bent backwards (fig 3a and b) The intragastric field is therefore no longer limited by "blind" areas—for example, the roof of the pyloric antrum in the J-shaped stomach is now visible by the combined effect of approximation of the objective and retrograde deviation of the angle of view brought about by flexing the instrument Gastro-enterostomy stomata can be more fully examined and lesions such as the lesser-curve ulcer in fig 3a can be viewed from more than one aspect

Fourthly, active control of movement has permitted the flexible part to be shortened and the upper rigid part to be lengthened as compared with the Schindler instrument The resulting reduction in the number of short-focus collecting lenses in the flexible part of the optical system has resulted in a considerable increase in the light-transmitting power and hence in a greatly enhanced brilliance of the endoscopic picture Endoscopic photography with the flexible gastroscope has therefore become practicable, and with the help of Mr H T Foot I have already been able to photograph an ulcer on the lesser curve

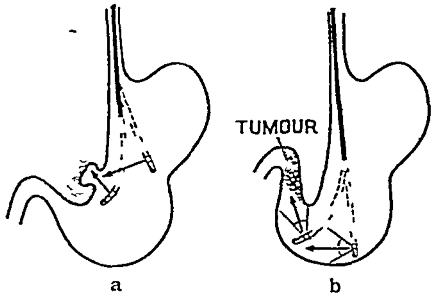

FIG 3—(a) A lesion can be viewed from two angles by using the flexion and retroflexion of the gastroscope (b) Flexion of the gastroscope brings the roof of the pyloric antrum in the J shaped stomach into view

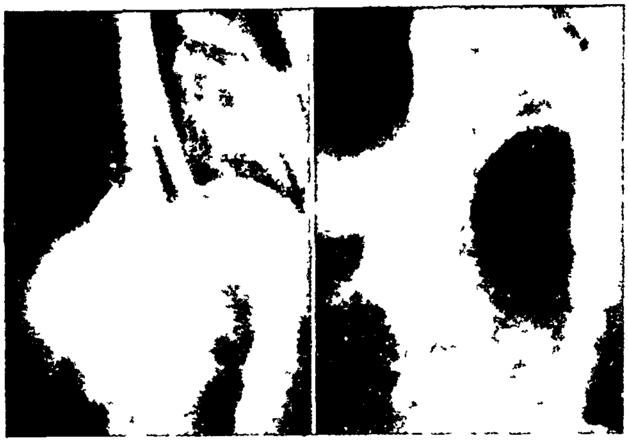

FIG 2—Gastroscope in two positions during examination of patient

The new instrument is 30 in long over all, and has an inch longer internal reach than the Schindler gastroscope, a property which I would have found useful in previous examinations of tall patients with gastroptosis

The flexible part consists of two concentric metal tubes constructed of left and right hand spirals respectively and the movement is controlled by means of two longitudinal wires between them at the back and front of the instrument A push and pull action of the wires controlled by a differential rack and pinion mechanism near the eye piece imparts the required degree of curvature to the flexible part but when the controlling wheel is free the instrument lies flaccid The lamp is incorporated in the rounded tip of the instrument and the whole is streamlined for smooth movement down the œsophagus The electrical and pneumatic connexions are combined at the upper end of the instrument so that only one attachment needs to be made to the instrument after it has been introduced into the stomach

I have been using this intrument exclusively for six months and have been gratified by the increased scope and ease in the examination of some hundred cases The simplification of technique in dispensing with gastric lavage and by using anæsthetising Desicaine lozenges for the throat, together with the use of the new instrument and the operating table attachment for the comfort and safety of the patient, combine to make gastroscopy an examination which can easily be performed on outpatients

SUMMARY

An improved gastroscope is described which by reason of active control of flexibility possesses the following advantages over existing passively flexible instruments .

(*a*) Greater safety of instrumentation
(*b*) Less likelihood of failure of instrumentation
(*c*) Abolition of "blind areas" in the stomach
(*d*) Ability to move the objective about inside the stomach so as to inspect any particular area closely at will and to do so from more than one angle
(*e*) Greatly increased illumination with less distortion of the image

I wish to thank Mr R Schranz, whose technical ingenuity contributed much to the production of the instrument, which is now being made by the Genito Urinary Manufacturing Co

---

A CHAIR OF CHILD SURGERY —Dr William E Ladd, clinical professor of surgery at Harvard and chief of surgical services at Boston Children's Hospital, has been appointed the first occupant of the chair of child surgery which will bear his name and which has been endowed by his friends This is the first Harvard professorship to be devoted to this subject

All the strains of hæmolytic streptococcus isolated from skin lesions and throats were examined for serological type (Griffith) The table shows the distribution of strains from the impetiginous lesions contrasted with the distribution of a series of throat strains from cases of scarlet fever occurring about the same period (July–September 1940) The strains recovered from the throats of 5 patients with impetigo were in each case serologically identical with the corresponding skin-strain, with one exception they were scantily present in the throat, and it is impossible to say whether or not the streptococci in the throat came before or after the skin-infection In no case was there an antecedent history of sore throat

DISTRIBUTION IN SEROLOGICAL TYPES OF STREPTOCOCCI ISOLATED FROM CASES OF IMPETIGO AND SCARLET FEVER

Type	1	2	3	4	8	11	12	14	25	30	Total
Impetigo	1	1	0	0	6	1	2	0	1	3	15
Scarlet fever	21	9	14	11	9	7	5	2	1	2	81

It will be seen from the table that there were 7 different serological types of streptococcus, all Lancefield A, isolated from the skin lesions of 15 patients, and that, omitting types 1–4 a somewhat similar distribution of serological types was found in impetigo and in scarlet fever during the same season The rarity of types 1–4, the common scarlatinal strains, in the impetiginous lesions in this series may be associated with the fact that the patients were all adults, de Waal (1941) has noted that types 1–4 streptococci are common in erysipelas in patients under 21 years, whereas the higher types occur more often in older patients

EPIDEMIOLOGICAL DATA

There is too little exact knowledge about the epidemiology of impetigo contagiosa and its relationship to other streptococcal infections In Denmark, an epidemic curve with its peak in late autumn has been described (Madsen 1937) In this country Newman (1935), from the examination of cases in a district of Southampton over a period of 2½ years, found a minimal incidence in summer followed by a rapid rise in early autumn from the 35th week to a peak in the 44th week; a slight drop in December was followed by another rise to maximum incidence in January Actually his graph of the seasonal incidence of impetigo bears a remarkable resemblance to the incidence-curve of scarlet fever (see *Lancet*, May 17, 1941, p 641), but ante-dating the latter by 3–4 weeks The age-incidence of impetigo in a series of 5124 school-children was also found to be similar to that of scarlet fever, 73 5% of the cases being in the 5–9 age-group (Ann Rep C M O, Board of Education, 1928, p 127) The severity of the clinical infection has, according to Newman, decreased greatly in the past 70 years Nephritis has been noted as a complication of impetigo These findings lend support to the views expressed by Dr C J Thomas (personal communication) that among London school-children impetigo and scarlet fever were sometimes closely associated, that children who had impetigo usually escaped scarlet fever, and that impetigo seemed to have the same relationship to scarlet fever as vaccinia has to smallpox

Two other points of epidemiological interest may be mentioned Impetigo is often regarded as a disease of dirty children This contention is denied by medical officers replying to a questionnaire from the C M O, Board of Education (1928) It probably owed its origin to the frequency of purulent dermatitis from scratching by lice-infested and scabious children, and the inclusion of these conditions under the term impetigo must be remembered in any epidemiological study. The other point is that impetigo is not apparently a highly contagious disease Newman found that contagion was not a conspicuous feature of the disease even in families, and in the reports to the C M O, Board of Education (1928), the spread of infection was blamed chiefly on the close contact, by sleeping together, of the school-child with his infected pre-school brother or sister Thus, exclusion from school of infected children is not likely to control incidence to any extent This apparent lack of contagiousness was also noted among the patients I examined last autumn In the first batch of admissions, there were four cases due to *Streptococcus pyogenes* type 8, and I naturally expected to find some association between these cases However, the men were found to belong to different units, and in no case in the series was any history elicited of close contact with another case Most of the patients attributed the onset of infection to a razor-cut or other abrasion

The seasonal incidence, the distribution on exposed parts of the body, and the apparent prevalence among troops all suggest that excessive exposure to the sun may be a factor in the ætiology of impetigo contagiosa It is a disease which although trivial in itself causes a great deal of school-absenteeism, and in time of war, a considerable amount of invalidity among troops There seems not to be agreement about the most effective treatment, indeed, several different antiseptics may have to be used on the one patient Crystal violet paint or a sulphonamide paste gave best results in our cases, but some lesions prove very intractable, and it is wise to ring the changes if there is little response after 2–3 days' treatment Thus, there are various reasons why impetigo contagiosa deserves much more concerted attention from the clinician, the epidemiologist and the bacteriologist

I wish to thank Dr W Gunn, medical superintendent of the L C C North-Western Hospital, for access to cases under his care, and Miss M C Rouse for technical assistance with the serological typing

A NEW GASTROSCOPE WITH CONTROLLABLE FLEXIBILITY

HERMON TAYLOR, M D, M Chir Camb, F R C S
ASSISTANT SURGEON TO THE LONDON HOSPITAL

GASTROSCOPY presents several problems which distinguish it from other endoscopic procedures The stomach must be entered through the relatively long, curved and delicate œsophagus, through which rigid instruments cannot be passed blindly without too great a risk of perforation It was for this reason that gastroscopy made so little headway until Schindler introduced the flexible instrument named after him Furthermore unlike the urinary bladder, for instance, the cavity of the stomach is not symmetrically disposed around the axis of the instrument, and the more distant recesses of the pyloric antrum, have hitherto been relatively inaccessible to close inspection, because all lateral movement of the objective inside the stomach has been impossible The further development of gastroscopy from the stage to which Schindler carried it has, therefore, demanded a solution of the problem of obtaining lateral movement of the objective within the stomach, without sacrificing the essential safety of introduction dependent on the passive flexibility of the instrument

This presented considerable technical difficulties, but experiments I have carried out during the last three years have resulted in the construction of a new instrument, the flexible part of which can be actively curled up or allowed to lie flaccid at will The instrument is illustrated in fig 1, and the radiograms in fig 2 show it in two different positions during the examination of a patient Passively flexible in all directions for introduction, it can be bent forwards and backwards in the plane of the objective up to the limits of optical flexibility This property endows the new instrument with several advantages

ADVANTAGES OF ACTIVE FLEXIBILITY

First, the new instrument enables the operator to overcome certain of the causes of failure of gastroscopy In reviewing a series of cases of gastroscopy with the Schindler instrument (*Lancet*, 1941, 1, 131) I found that the examination was partially or wholly unsuccessful in 9% of all cases The great majority of

Proteus X2 O alone indicates a diagnosis of tick-bite fever s it occurs in South Africa" (*Rep S Afr Inst med Res* 939) In India, Sarkar (1939) also records a case of a typhus-like fever with agglutination of *X2* O only, but the vector could not be determined In Hamburg, Ruge (1939) has described a case of typhus-like fever in a sailor whose serum agglutinated *X2* O alone

In our case the most probable source of infection was the ship from the Argentine which the patient was unloading, and it should be noted that Fialho (1932) has described a typhus-like fever occurring in São Paulo, South America, which has been shown to be immunologically identical with the Rocky Mountain spotted fever of North America (Parker and Davis 1933, Dyer 1933) The infection has been shown to be spread by local ticks, probably mainly by the horse-tick, *Amblyomma cajennense* (Lemos Monteiro and da Fonseca 1933) This tick is widespread where the disease is common and readily attacks both rodents and man It seems possible that infected ticks were brought on board by rats or among the hides and that they were driven from these when the hold became flooded and the rats drowned On arrival in port an infected tick may have attached itself to the patient, inoculating him with the typhus rickettsiæ In São Paulo typhus, *X19* O antigen is agglutinated typically to a high titre, there being a relatively low titre for *X2* O We therefore do not feel justified in suggesting more than a provisional diagnosis of a tick-borne typhus-like fever which may be related to São Paulo typhus or Rocky Mountain spotted fever—diseases which are in any case closely allied

Other points of interest are the agglutination of *Bact paratyphosum B* H and the positive Wassermann reaction with a negative Kahn result Wilson (1909) was the first to emphasise the frequency of positive Widal reactions in cases of typhus and this has been repeatedly confirmed since Boyd (1935), in describing 14 cases of typhus-like fever occurring in India, in which *X2* O was mainly agglutinated, noted that one or more antigens of the enteric group were commonly affected also Thus in 9 out of 14 cases there was a rise in agglutinins for *Bact paratyphosum B* H Tests for syphilis were carried out in 4 cases and in one of these a result was obtained similar to the one we report The Wassermann reaction was positive and the Kahn test negative during the fever Both were found to be negative during convalescence Finally, in our case there was a definite increase in monocytes, a feature which is said to occur in Rocky Mountain spotted fever and other rickettsial diseases (Whitby and Britton 1939)

SUMMARY

The clinical features and serological reactions of a case of typhus-like fever occurring in a dock labourer in a Scottish port are described

The case was thought to belong to the tick-borne group of typhus-like fevers because of the strong agglutinin response for *Proteus X2* O with negative reactions to *Proteus X19* O and *XK* O This type of Weil-Felix reaction, although unusual, has been recorded in cases of typhus-like fever known definitely to be tick-borne in North America and South Africa

The patient was possibly infected by one or more ticks which had travelled from South America, either among a cargo of hides or infesting one of the rats on the ship he had been unloading

We have to thank Prof D M Dunlop, Prof T J Mackie, Lieut Colonel E D W Greig and Dr Alexander Joe for their help

ADRENALINE-ASCORBATE SUSPENSIONS IN BRONCHIAL ASTHMA

ALEXANDER KENNEDY, M D Lond , M R C P , D P M
MAJOR, R A M C , CHIEF ASSISTANT FOR PSYCHOLOGICAL MEDICINE,
ST BARTHOLOMEW'S HOSPITAL, LONDON

IN the immediate treatment of acute bronchial asthma, no therapeutic agent has been found which entirely replaces the injection of adrenaline The absorption and destruction of this drug are, however, so rapid that its effects are brief and difficult to control In long attacks normal respiration can only be attained for any length of time by repeated injections, each of which may subject the patient to the unpleasant sensations associated with a sudden excess of adrenaline in the circulation and yet only relieve the attack for an hour or two at the most This may to some extent be avoided by giving dilute infusions of adrenaline in normal saline or by the continuous method advocated by Hurst (1929) Such techniques require continuous skilled attention and completely immobilise and invalidise the patient

The discovery of ephedrine has allowed a large number of asthmatics whose attacks are predominantly nocturnal to obtain enough rest at night to permit of their following a normal occupation by day But except in mild cases, or where it can be given before the attack commences, this drug often has an insufficiently powerful bronchodilator action, unless it is given in doses which produce symptoms of intoxication It has also the considerable disadvantage that the patient may develop tolerance and require increasing doses to secure relief

The chronic asthmatic, even if unaided by desensitisation methods, can often lead a normal life by the intelligent use of adrenaline and ephedrine In cases where there is permanent but not very severe pulmonary damage, and complete recovery is unlikely, this self-treatment is to be encouraged if by its means the patient can be prevented from allowing the disability to narrow the scope of his activities until he slips gradually into permanent invalidism By reducing the amount of dyspnœa, symptomatic treatment of this kind will delay the progress of emphysema and relieve the strain on the heart When ephedrine alone fails to be effective, or when periods of abstinence from it are indicated by increasing tolerance or signs of chronic intoxication, adrenaline injections become necessary When these have to be used at night sleep is interrupted not only by the injections themselves but also by the palpitations and shakiness which may follow them After several nights the patient may fail to wake up for his injection when the attack comes on and only becomes aware that he has had an attack when he finds himself too exhausted to go to work next day It is clear that any method of securing a continuous and uniform adrenaline-like action by a single injection on retiring would be of great assistance in such cases

The object of such a technique must be to form in the tissues a reservoir of the drug from which gradual absorption can take place Keeney (1938a) introduced the use of oily suspensions of adrenaline and reported favourable results (1939) Spain, Strauss and Fuchs (1939) added gelatin to solutions of adrenaline and found that less frequent injections were necesary to keep the patient free from attacks These methods, while allowing of a somewhat slower action, have in themselves certain disadvantages The object of the present work was to find a method of administering adrenaline which renders its liberation into the circulation as slow as possible and its rate of absorption as even as possible during the period of its action The preparation finally arrived at consists of a concentrated suspension of dry adrenaline base with ascorbic acid in arachis oil, anhydrous wool-fat and a small quantity of white wax

DEVELOPMENT OF THE METHOD

The simple suspensions of adrenaline in oil, as used by Keeney, Pierce and Gay (1939), Murphy and Jones (1939) and others, although marking a great advance in the symptomatic treatment of asthma and hay-fever, possess a number of disadvantages When they are given frequently over a long period, a considerable

POSSIBLE CASE OF TICK-BORNE TYPHUS

IN A SCOTTISH PORT

G B LUDLAM,
M B EDIN, D T M & H
ASSISTANT IN BACTERIOLOGY TO THE UNIVERSITY OF EDINBURGH

I R C BATCHELOR,
M B EDIN
HOUSE PHYSICIAN AT THE ROYAL INFIRMARY OF EDINBURGH

A J RHODES, M B Edin, M R C P E
LECTURER IN BACTERIOLOGY TO THE UNIVERSITY

It is now generally recognised that there occur in many parts of the world rickettsial diseases which resemble true exanthematic or louse-borne typhus in certain important respects These infections are generally classed together as "typhus-like" fevers and include, among others, endemic murine typhus (flea-borne), tsutsugamushi disease and rural typhus of Malaya (mite-borne), and such tick-borne fevers as Rocky Mountain spotted fever and fièvre boutonneuse of the Mediterranean area

The Weil-Felix agglutination test—in which the patient's serum is tested against the "O" antigens of three varieties of *Proteus* (*X19*, *X2* and *XK*)—is often of the greatest value in elucidating the diagnosis of cases of typhus or typhus-like fever, and the various types of reaction which may be encountered are as follows

In the classical louse borne typhus, as well as in flea borne typhus like fever, the X19 antigen is mainly concerned and is agglutinated to high titre In the mite borne typhus like fevers (e g, of Malaya) the XK antigen is usually agglutinated to high titre Finally, in the tick borne fevers the more usual finding is agglutination, usually to a low titre, with all three antigens, X19, X2, and XK, in certain cases, however, only the X2 antigen may be agglutinated

It is the object of this paper to describe a case occurring in a Scottish port which is considered, both on clinical and serological evidence, to belong to the tick-borne group of typhus-like fevers

CASE-HISTORY

A dock labourer at a Scottish port was engaged from Sept 25 to Oct 5, 1940, in unloading a cargo of hides from the Argentine The hold was water loggod and many dead rats were floating in it, there were also many living rats On Oct 17 twelve days after ceasing work on this cargo, he was suddenly taken ill, feeling very weak and losing his appetite A week later he noticed a rash on his body and limbs and became deaf There was also some dysuria in the early stages of the illness, and he had a slight epistaxis about a week after the onset

On Oct 26 he was admitted to hospital At that time his main complaint was of headache His face was slightly flushed and puffy, his complexion sallow, the sclera was somewhat yellow, and the conjunctiva injected, both pupils were much contracted and photophobia was pronounced, the tongue was extremely dry and furred The rash involved the trunk and limbs, although the palms and soles were unaffected The lesions were reddish brown, macular, and slightly papular, and were associated with petechiæ which were most numerous on the flexor aspects of the elbows A few small shotty glands could be felt in both axillæ There was evidence of bronchial catarrh and some nerve deafness There was no palpable hepatic or splenic enlargement, and the tendon-reflexes were unaffected The nerve deafness persisted and was severe The patient became drowsy four days after admission, and remained so for another three or four days The rash began to fade a week after admission and had almost disappeared at the end of a further five days, some brown staining of the skin remained For the first four days the temperature varied between 100° F and 102° F, later becoming remittent with a variation of about 2 5° F during the 24 hours, twelve days after admission it had settled to between 99° F and normal For the first week the pulse rate varied between 88 and 115 and thereafter between 75 and 90

Laboratory findings—Icteric index 20 on Oct 28, 11 on Nov 2 Urea nitrogen, 28 mg per 100 c cm of blood on Nov 2 Urine, on Oct 24, contained urobilinogen, a trace of albumin, no sugar, and no bile The centrifuged deposit showed a very few granular casts but no red or pus cells Fæces gave a negative benzidene test on Oct 28 Blood-sedimentation rate (Westergren) was 93 mm per hour on Nov 6 Blood count on Nov 4 red cells 3,950,000, some anisocytosis, Hb, 76%, colour index, 0 96, reticuloc under 1%, white cells 8400 (polymorphs 45%, lymphoc (mainly large) 33%, monocytes 19%, plasma cells 2 eosinophils 1%), no diminution in the platelet count

Animal inoculations were carried out with a view to exclu ing leptospirosis as a possible diagnosis, guineapigs were inoculated intraperitoneally with blood on Oct 28 and with urine on Oct 28 and Nov 4, but no leptospiral infection developed On Nov 6 whole blood was injected intraperitoneally into 2 male guineapigs, they showed no fever or scrotal reaction, the testes were removed and a suspension injected intraperitoneally in another pair of guineapigs, with negative results Rats from the hold of the ship were also examined because it was thought that the patient might have become infected from ticks infesting rats The brains of 6 rats were removed, a suspension was prepared, and 2 male guineapigs were injected intraperitoneally No fever or scrotal reaction, however, was noted, and the animals remained in good health

Test	Oct 28	Nov 1	Nov 4	Nov 6	Nov 17	Feb
Weil Felix—						
X2 O		1/240	1/480	1/480	1/240	1/60
X19 O		Neg	Neg	Neg	Neg	Neg
XK O		Neg	Neg	Neg	Neg	Neg
Widal—						
Bact paratyph B H			1/480		1/240	1/60
Tests for syphilis—						
W R				+++		±
Sachs Georgi				1/32		Neg
Kahn				Neg		Neg
Leptospira agglutination	Neg			Neg		

Serological tests (see table) gave the following interesting results

(*a*) A positive Weil Felix test for the *X2* O antigen only, the titre at one stage being 1/480

(*b*) Strongly positive Wassermann and Sachs Georgi tests which became almost negative in three months' time without antisyphilitic therapy and in the absence of any evidence of syphilis The Kahn test was negative on both occasions

(*c*) A positive reaction in the Widal test for *Bacterium paratyphosum B* H antigen This titre became considerably reduced in three months, and there was no evidence of paratyphoid infection The remaining antigens in the Widal test were quite unaffected (*Bact typhosum* O and H, *Bact paratyphosum A* H, *Bact paratyphosum B* O, and *Brucella abortus*)

(*d*) Agglutination tests for leptospiral infection were carried out on two occasions with negative results

DISCUSSION

On admission the case was provisionally diagnosed as leptospirosis, but negative agglutination and animal inoculation tests led to a revised diagnosis A tentative diagnosis of typhus was made on clinical grounds and this was supported by the result of the Weil-Felix test which showed agglutination with *Proteus X2* O antigen and a rise in titre when repeated three days later

Louse-borne typhus was at one time common in Great Britain but is now rare Gray, Peters, and Davies (1938) reported a case of typhus from Bristol in which the patient had handled imported bags of flour, during the fever his serum agglutinated *Proteus X19* O antigen to a high titre This was probably a case of murine typhus, since in this disease the antigen *X19* O is agglutinated to a high titre, and the infection occurs typically as a sporadic infection in men handling food-stuffs, especially grain Louse-borne infection could not, however, be excluded The case we have described gives an entirely different type of Weil-Felix reaction, and for this reason we do not believe a diagnosis of either louse-borne or flea-borne typhus can be maintained

The agglutination of the *Proteus X2* O antigen points to the disease belonging to the tick-borne group of typhus-like fevers, although it is unusual for the *X2* O antigen alone to be agglutinated However, Davis and Parker (1938) report that in certain cases of Rocky Mountain spotted fever the *X2* O antigen may be agglutinated alone This type of reaction has also been recorded in South Africa "Our experience this year has confirmed the finding that the agglutination of adrenaline is used two or three injections may be needed during the night These, with the period of nervousness and palpitation which may follow them are themselves exhausting A short course of nightly injections of adrenaline suspension often restores normal routine by allowing of an unbroken period of sleep

Chronic asthma—In asthmatics with chronic bronchitis winter exacerbations often lead to an annual period of invalidism This can be considerably shortened, and the bronchitis can be allowed to clear up unhampered by spasm by using this form of adrenaline With the patient in bed four injections of 0 3 c cm can be given during the 24 hours until the dose can be reduced

Status asthmaticus—In this condition the expiratory dyspnœa is probably due to a combination of bronchiolar spasm with obstruction from the presence of œdema and exudate in the bronchioles It is often resistent to intermittent injections of adrenaline solutions By reducing œdema by the hypertonic sucrose method of Keeney (1938b), and then keeping the patient free of further attacks by injections of adrenaline-ascorbate suspension it has been possible to relieve several severe cases of status asthmaticus These patients respond poorly to adrenaline until a fairly large quantity has been given, and large doses are therefore justifiable in the early stages of treatment My routine is to give 100 c cm of 50% sucrose intravenously, by means of a continuous delivery syringe, at once, together with 0 3 c cm of suspension If this is well tolerated, a further 0 3 c cm is given after 2 hours Thereafter 0 4–0 6 c cm of suspension is given every 6 hours until improvement in the patient's condition justifies reduction in dose or lengthening of the interval

Adrenaline-ascorbate suspensions have been found most beneficial in the types of case described, but there are clearly many other indications in conditions of allergic origin

SUMMARY

A method is described of preparing a suspension of adrenaline and ascorbic acid so that absorption of the adrenaline into the circulation is delayed and its action prolonged

This suspension has proved particularly useful in cases of chronic bronchial asthma with frequent nocturnal attacks and in status asthmaticus

I am indebted to several physicians for making clinical trials on asthmatic patients, and to Mr A Ogden, M P S, for his assistance in the task of preparing the numerous suspensions tried

Reviews of Books

Tomography

By J B McDougall, M D Glasg, F R C P E, F R C S E, medical director of Preston Hall, Maidstone London H K Lewis and Co Pp 73 21*s*

This is the first separate volume which has appeared in this country on tomography, or as some call it planigraphy, stratigraphy or laminagraphy By means of an apparatus which allows the X-ray tube and the film carrier to be moved in opposite directions during the exposure it is possible to "focus" the rays in any selected body plane The planes above and below this are blurred and do not materially alter the detail of the selected plane Dr McDougall's atlas consists of 110 radiograms most of which indicate the value of tomography in showing up tuberculous cavities concealed by local areas of consolidation, by thickened pleura and by operative procedures on the chest wall There are a few illustrations of bronchiectasis and bronchial stenosis but none of lung abscess The use of tomography was extending rapidly before the war and great progress was being made with it in many chest diseases and especially in pulmonary suppuration It seems to be the ideal method for localising foreign bodies in the lungs and mediastinum

Starling's Principles of Human Physiology

(8th ed.) By C Lovatt Evans D Sc, F R C P, F R S London J and A. Churchill Pp 1247 32*s*

As the number of physiological textbooks increases, "Starling" becomes more indispensable, for it is different in character from any of them and from any which are likely to be produced in the future Its strength is not derived from unnoticed omissions There are still numbers of chapters on subjects like the cell, biochemical principles biophysical principles, defence of the organism against infection, and heredity, while the human importance of things like milk, everyday nutrition and pregnancy is not forgotten All this takes up space and prevents the expansion of sections on the big systems but it dovetails the book firmly into related sciences and tells the reader better by its scope than by any definition just what is physiology The special senses are over-represented by the 120 or so pages which they fill but this section by Hartridge is so complete in itself, in spite of some recent pruning, that it would be a pity to spoil it by attempting to compress it into a small space Hartridge's own theory of visual acuity is a welcome addition In another dimension the book has its roots in the beginnings of modern physiology The reader who uses the references, liberally scattered through its pages, will indeed find the most recent contributions to the subject, but he will also make the acquaintance of the old masters and thereby benefit

The most striking feature of this edition is Lovatt Evans's complete rewriting of the section on the central nervous system which, profusely illustrated, is now fully in keeping with modern ideas A great deal of work has also been devoted to the sections on reproduction endocrine organs and vitamins and changes are discernible throughout This edition is larger than and an improvement on all its predecessors The style remains direct, emphasising ever the concrete experimental result This makes it a book to be studied rather than read—a compliment to the present generation of students It will remain a never-failing source of factual information for their teachers The greatly increased number of illustrations and the replacement of old ones are further improvements

The Cambridge Evacuation Survey

Edited by Susan Isaacs with the coöperation of Sibyl Clement Brown and Robert H Thouless London Methuen and Co Pp 231 8*s* 6*d*

This is a war-time study in social welfare and education based on two selected groups of 725 out of 3000 London children evacuated to Cambridge in the first days of the war The period covered by the investigation ended in July, 1940, so that in some measure the story seems already out of date, dealing as it does with months before air-raids on any considerable scale had begun None the less it is a valuable study of the complex problem of evacuation from the various points of view of officials and other workers, parents, children foster-parents, teachers and billeting officers Credit is given for the admirable organisation of the actual trek from London, but it is suggested that some failures might have been avoided "if human nature had been taken into equal account with geography and railway time-tables" Children sent to Cambridge were fortunate in several respects not only were there exceptional facilities for their recreation but from an early date a child guidance clinic was available, and an emergency hostel was established for children needing special treatment There is an illuminating chapter entitled "What the children say" amount of oil has to be injected into the patient, and this is not very rapidly absorbed. The adrenaline is apt to be absorbed much more rapidly in the first half-hour after injection than later on, and symptoms of collapse have been recorded from absorption of almost all the adrenaline content of the injection at once (Dorwart 1940). Symptoms referable to sensitivity to the vehicle (peanut-oil) have also been recorded by Cohn (1939). Continual shaking is necessary to keep the adrenaline suspended, and owing to sedimentation uniform dosage cannot be assured. In oily suspension adrenaline base is fairly readily oxidised and loses potency slowly even when kept in a cool, dark place. Contamination of the syringe with small quantities of water, causing solution of the drug, may allow a large dose to enter the circulation at once, resulting in severe symptoms of overdose.

During the past two years a large number of personal experiments, together with clinical trials of the products which produced no harmful symptoms, have allowed a preparation to be evolved which minimises a number of these faults. The effects of the drug were assessed by the changes in blood-pressure and blood-sugar, by the subjective sensations, and, in the case of the patients, by its relief of attacks of asthma. These methods have no pretensions to accuracy but were a help in forming a general clinical impression.

The problem was approached in two ways, chemical and physical, and both contributed to the final result.

Compound of adrenaline used.—Zinc, which retards the absorption of adrenaline, could not be used, since it allows of rapid oxidation and loss of potency (Kohn and Bulger 1937). It was hoped that by associating the adrenaline base with a fairly complex acid its absorption might be retarded without this happening. Adrenaline forms salts with mineral acids and with boric acid, and these are less liable to oxidation than the base. For a number of reasons it was decided to associate the adrenaline with ascorbic acid, and it was found that actual combination took place. Ascorbic acid considerably retards the oxidation of adrenaline, both in solution and in suspension. Owing to the presence of a double bond it is a powerful reducing agent; it was, in fact, first discovered as such in the suprarenals by Szent-Gyorgyi in 1928. When present in excess it keeps the suspension sufficiently acid to discourage oxidation, which does not take place in adrenaline solutions more acid than pH 3. Ascorbic acid is, moreover, non-toxic, and favourable results have been described from its independent use in asthma (Epstein 1936, Hochwald 1936, Cintra 1939). The theoretical reasons for its use in asthma have been summarised by Hunt (1938). In view of the special usefulness of the suspensions in nocturnal asthma its effect in promoting sleep is of interest, while its favourable effects in cardiac failure (Evans 1938) are worthy of note in view of its use in cases of status asthmaticus. In practice it was found that suspensions of adrenaline base with ascorbic acid in excess deteriorated very slowly and were non-irritant to the tissues in concentrations under 15 mg. per c.cm. of the acid. The suspensions were made of a mixture of the finely divided powders, no attempt being made to isolate the ascorbate in quantity.

The base.—For self-administration, it was hoped to inject the suspension through as fine a needle as possible, so that the choice of a base was limited. Olive oil and arachis oil were both sufficiently thin, and the latter was chosen as more constant in composition. Simple suspensions sedimented rapidly, and when enough wool-fat was added to prevent this the mixture became too thick. The quantity of wool-fat necessary was greatly reduced by addition of a very small quantity of white wax. With these suspensions containing wax, absorption seemed to be much slower, as if it had some protective effect on the adrenaline. The base finally used was thin and easily sterilisable. On account of the difficulties with sterilisation, the work of Spain, Strauss and Fuchs on retarding absorption with gelatin was not repeated.

Arachis oil, though absorbed as rapidly as most vegetable oils, is not very rapidly removed from the tissues. After an injection of 2 c.cm. into the deltoid, over 1 c.cm. was aspirated a week later; this was full of polymorphonuclear cells, suggesting that it had been walled off in the tissues. For this reason it was thought advisable to make the bulk of the injections as small as possible. It was found that increasing the concentration of the suspension as far as 10 mg. adrenaline per c.cm. did not greatly accelerate absorption, and this strength finally used. The average dose therefore contains a little over 0.2 c.cm. of oil.

PREPARATION AND ADMINISTRATION

The efficiency of the suspensions depends considerably on the technique of preparation. The formula is:

Adrenaline base (in very fine powder)	0.010 g.
Ascorbic acid (in very fine powder)	0.015 g.
Cera alba	0.020 g.
Wool fat (anhydrous)	0.040 g.
Ol. arachis B.P.	1 c.cm.

The white wax and wool-fat, with a little of the arachis oil, are sterilised at 150° C. for an hour in a hot-air oven and allowed to cool, the rest of the oil being sterilised separately in a similar manner. The wool-fat must be anhydrous and the use of lanolin in one sample led to very rapid absorption and alarming symptoms of overdose. The adrenaline and ascorbic acid are ground to a fine powder in a previously sterilised mortar, under aseptic conditions, and are then triturated with some of the cooled arachis oil. The mixture of wool-fat, wax and oil is added to form an homogenous suspension. This is at once transferred to dark amber glass vaccine bottles, each of which contains 3 c.cm. of glass beads and are filled only half full to allow for shaking. They are then thoroughly agitated. The suspension is drawn, when required, through a skirted rubber cap which can be covered with a screw cap to exclude moisture. The bottles should be stored in the dark, in a refrigerator.

The injections are made with a dry 1 c.cm. record syringe. The bottle is warmed before use, but not above 50° C. If properly prepared the suspension can be injected through a 6/10 bore needle, a feature of special value when it is to be given by the patient himself. In hospital the injection is made deep into the gluteus medius, or, where there is room, into the deltoid. Patients can be taught to give their own injections into the region 2 in. below the crest of the ilium, using alternate sides and moving backwards 1½ in. with each injection. Injections must be given as deeply as possible and the skin must be rubbed afterwards to prevent leakage of oil. For filling the syringe a separate large bore (10/10) needle may be used, to prevent air bubbles from entering the suspension.

The average dose is 0.3 c.cm. (i.e., 3 mg. of adrenaline base). Its effects are comparable to those of a series of injections of 0.5 c.cm. of liq. adrenaline hydrochlor. and last for 6–8 hours. During the first 2 hours the intensity of action is sufficient to arrest an attack of asthma, and for the rest of the time it is usually sufficient to prevent one from coming on. The maximum effect occurs ¼–¾ hours after injection. During this period the patient may feel palpitations, tremor of the hands and a feeling of tension, and may look a little pale. As the suspensions were improved, these symptoms became less marked and came on at an increasing interval after injection. In many cases, especially in nocturnal asthma, it is possible to avoid these side-effects altogether.

Patients vary considerably in response to adrenaline. For this reason the initial dose should always be 0.1 c.cm., except in status asthmaticus, where adrenaline is usually tolerated well, and the first dose may be 0.5 c.cm., or rarely 0.6 c.cm. The effects of an excess of adrenaline in the circulation may be due to overdose, contamination of the suspension with water, or to injection into a vascular area. They consist of pallor, severe palpitations with precordial distress, air-hunger and faintness. The danger is not great, and the patient should be kept as still as possible. There is no practical physiological antidote.

INDICATIONS

Nocturnal asthma.—The type of case in which adrenaline-ascorbic suspensions have proved most useful is the chronic asthmatic with some emphysema, who can work by day but whose attacks are predominantly nocturnal. Many of these patients find that taking ephedrine at night is not always sufficient to prevent attacks. When a cold or some dietary indiscretion has made the attacks more severe for a few days the patient becomes too exhausted to go to work in the morning. If aqueous

THE LANCET

LONDON: SATURDAY, SEPTEMBER 6, 1941

AN ARMY OF CHOICE

THE well-acted despair of the traditional sergeant-major when faced with a new bunch of recruits was not a grossly exaggerated caricature of his feelings. The job of welding a collocation of men of widely dissimilar intelligence, experience and interests into a corporate team with uniform standards of skill and behaviour was never a mean one. Today, when the soldier is expected to handle valuable mechanical equipment successfully, the task is much more complicated. Mental fitness, as the U.S.A. medical induction boards are now realising, is far more difficult to assess than physical fitness. The twenty-second report of the Select Committee on National Expenditure comes to grips with the problems of allocating man-power in the Army and woman-power in the A.T.S. A report from the subcommittee on Army Services has been adopted in which the system of selection by testing for intelligence and aptitude is strongly advocated. Selection by testing is a new principle in the British Army, and could only be given its fullest value as the report points out if it had already been in use for twenty years. Difficulties and prejudices will have to be overcome, many of the tests will have to be devised from day to day, and revised equally freely. Two types of test will be needed: a simple intelligence test, to discover whether a man or woman is suitable for specialised training, and a special-aptitude test to decide what his particular job should be. Tests of the second type will have to be designed by people with wide experience of the jobs to be done, and for that purpose, as we have already noted, a special directorate has been set up in the War Office to work out the method of selection. The committee would limit such tests at present to technical bodies like the Anti-Aircraft and the Royal Armoured Corps.

The time allowed for examination by medical boards is short; the committee therefore advise that the examiners should have before them the National Health Insurance records of the men they are to examine. Recruits should then take, either at once or on an arranged day, a simple "civilian" test of mental capacity, conducted for the Services by the Ministry of Labour and National Service. Thus men would be graded mentally before being posted to a corps. Under the present system the recruit is seen by the interviewing officer, who in times of peace is able to talk with each man long enough to form some estimate of his capacities; in war, the interview is reduced by pressure of time to a few questions, and since transfer after posting is difficult a man's whole future in the Services may depend on his answers. A preliminary test at this stage would make it possible to post men to corps roughly appropriate to their capacity. What might be achieved by such a test is indicated in a table of vocational categories quoted in the report, drawn up fifteen years ago by (what is now) the Industrial Health Research Board. Later it may be possible to send all recruits on joining to a central depot where they could be more carefully graded for special work. Officers too, should be selected from those whose intelligence, as measured by tests, exceeds a certain level; the other qualities essential in an officer would be ascertained from the reports of commanding officers, as at present.

Mental ratio	Vocational category	Per cent of adults
Over 150	Highest professional and administrative work	0.1
130–150	Lower professional and technical work	3
115–130	Clerical and highly skilled work	12
100–115	Skilled work, minor commercial positions	26
85–100	Semi skilled work, poorest commercial positions	33
70–85	Unskilled labour and coarse manual work	19
50–70	Casual labour	7
Under 50	Institutional cases (imbeciles and idiots)	0.2

The committee make similar proposals in regard to the Auxiliary Territorial Service. This was set up to save man-power in the Army wherever possible, and it is now taking over, in connexion with anti-aircraft and other units, some specialised combatant duties which require a high standard of intelligence and training. The committee feel that so far the A.T.S. has been hampered by the type of work given to it, and by the failure to give its members sufficient chance to gain positions of responsibility. In the selection of personnel for such responsible posts they again advocate the use of a preliminary test of ability at an early stage. Special tests, they think, should be given to potential drivers and clerks, and to anti-aircraft and signals personnel. Recruits will probably do better in tests if they are allowed to settle down for a few days before taking them, and the committee therefore advise that the tests should be given at the reception depots, not at the recruiting offices. It has been found that candidates for selection as officers seldom appear at their best before selection boards; and to avoid the loss of potential officers from this cause it is suggested that candidates should be sent in larger numbers to the Officer Cadet Training Units, where those who are unsuitable can be gradually eliminated by fortnightly tests. Those who fail to reach the required standard should be returned to their units or—preferably—posted elsewhere.

A NEW WAY OF IDENTIFYING INFLUENZA VIRUS

WE continue to learn of strange pranks which viruses can play. Dr. G. K. HIRST[1] at the Rockefeller Foundation's Laboratories in New York has lately shown that certain fluids containing influenza virus have the property of specifically agglutinating fowl's red cells. He had been inoculating chick embryos with the virus, and, while removing allantoic fluid from infected embryos, noted that blood reaching that fluid from accidentally ruptured vessels became agglutinated. Further study showed that this did not happen in control, uninoculated, eggs but that infected allantoic fluids could be considerably diluted and still show the effect. The agglutination was rather loose and was easily broken up by shaking.

Cerebrospinal Fever

By **DENIS BRINTON**, D M Oxfd, F R C P, physician in charge of department of nervous diseases, St Mary's Hospital, Paddington Edinburgh E and S Livingstone Pp 163 8*s* 6*d*

THIS pleasantly written little book marks a distinct departure from the accounts of cerebrospinal fever in textbooks, even in those issued as late as 1940 Here the old wood has been ruthlessly cut out, and the reader is presented with the facts elicited by modern clinical research A correlation of symptoms with morbid anatomical changes in line with these researches has been attempted, and the new chemotherapy is explained in full Since this has transformed the evolution of the disease, dreary descriptions of obsolete types and obsolete treatment have dropped out The author follows closely the work and technique of Banks, his own experience is based on the epidemic of 1940 in the R A F and does not include the disease in infants and children There are few typographical errors, but on p 105 in a reference to the Vacoliter drip method of giving glucose saline it is stated that it is usually necessary to expose a vein this must be a slip for "unnecessary"

British Encyclopædia of Medical Practice

Surveys and Abstracts, *Cumulative Supplement* Edited by SIR HUMPHRY ROLLESTON London Butterworth and Co Pp 596 and 282 27*s* 6*d* together

THE Cumulative Supplement and the Surveys and Abstracts are arranged in two books The first new work done since the publication of the last supplement is summarised and arranged under the same headings, with cross-references to the original volumes The second book contains critical surveys of recent work, a special section on drugs, and abstracts of medical literature of the last year by British and foreign authors The books are admirably constructed and well illustrated, but the text is sometimes confused by the large number of references to other volumes in the series Inevitably, the critical surveys deal with the effect of war on medicine, but the general practitioner, for whom the books are presumably intended, still spends most of his time treating such conditions as measles and bronchopneumonia The sections on digestive diseases in soldiers and injuries to the ear in war-time, for example, might have been shorter The abstracts, however, are instructive, brief and well written The alphabetical arrangement of the supplement is perhaps not ideal, the busy man could probably find the facts he needs more readily if they were arranged under systems and regions as in the standard textbook At present he is confronted with facts about menorrhagia sandwiched between meningitis and mental deficiency

Manual of Clinical Chemistry

By **MIRIAM REINER**, M Sc, assistant chemist to the Mount Sinai Hospital, New York New York Interscience Publishers, Inc Pp 296 18*s*

THIS book describes the biochemical methods for analysis of blood, urine, fæces, cerebrospinal fluid and gastric contents Several other such works are available and a new textbook on this subject may scarcely seem warranted, but this small manual certainly gives all the necessary information conveniently The book is purely technical and likely to interest chiefly technicians and practitioners who carry out their own analysis

Physical Therapy for Nurses

(2nd ed) By **RICHARD KOVACS**, M D London Henry Kimpton Pp 335 15*s*

THIS useful American manual has been revised and rearranged, and chapters on the history of physical therapy and short-wave diathermy have been added and the wealth of information compressed into this small volume will be equally valuable for medical students and nurses In some chapters too much has been attempted, so that accuracy has been sacrificed The wisdom of introducing advanced physics into a simple exposition of physical methods of treatment may be doubted and there are a few statements which are controversial—for instance the remark that ultraviolet light increases the number of red blood-cells The failure to adopt routine erythema skin-tests is to be deprecated, especially when treatment is undertaken by non-medical workers. There are many excellent diagrams and numerous illustrations of apparatus and methods of treatment, and the sections on hydrotherapy and massage are decidedly useful

---

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

THE summer meeting of this association was held at the Robert Jones and Agnes Hunt Orthopædic Hospital, Oswestry, on Aug 9, under the presidency of Prof T P MCMURRAY, when the following short papers were read

Mr N W **NISBET** (Oswestry) in a twelve year period had treated by traction 26 patients with *slipped upper femoral epiphysis* There had been a long period of intermittent symptoms before medical advice was sought and radiograms in two planes always revealed displacement Traction did not change the position in cases with mild displacement, but sometimes produced considerable, although not complete, correction in those in which displacement was severe Prolonged heavy traction appeared to have an adverse effect on the hip and knee joints and in this series seemed to have some responsibility for the development of arthritis in the hip joint Mr Nisbet concluded that —

1 When displacement is slight no effort should be made to correct it, the hip should be protected and weight bearing avoided until the epiphysis had fused In this way normal function can be achieved The insertion of a Smith Petersen nail might hasten recovery, provided it did not damage the blood supply of the capital epiphysis

2 When displacement is pronounced and not of long duration sufficient correction may be achieved by cautiously applied traction to ensure a satisfactory, although not perfect, result

3 If severe displacement cannot be corrected by traction or is of long duration the best results follow a subtrochanteric osteotomy to correct deformity, and this treatment is preferable to persistent and vigorous traction

Mr N L **CAPENER** (Exeter) described a *pseudo-fracture of the tibia* A child aged seven had complained for a month or so of discomfort about the ankle Radiograms were negative Three weeks later a further radiogram showed a crack in the lower diaphysis of the tibia with subperiosteal new bone formation which suggested a "fatigue" fracture Recovery was uneventful Mr Capener also discussed *operative treatment of intra articular fracture of the upper end of the tibia* He maintained that because of the soft texture of the cancellous bone in this region bone-pegs and screws are mechanically inefficient He showed radiograms of 3 patients treated by wire applied circumferentially around the upper end of the tibia through two incisions, while longitudinal skeletal traction was applied Early active movements were initiated and the functional and anatomical results were most gratifying

Mr **RONALD FURLONG** (London) demonstrated the value of *arthography* in *congenital dislocation of the hip* He showed a series of radiograms in which a contrast medium (Per-abrodil in pure solution) had been injected within the capsule before and after reduction of the dislocation, and indicated the valuable information which could be gained about the possibilities of a successful manipulative reduction, the accuracy of reduction and the development of an adequate acetabular roof

Mr **DENYS WAINWRIGHT** (Stoke) compared 20 patients treated for *fracture of the olecranon* by excision of the detached fragment and efficient repair of the extensor apparatus with 20 treated by other methods, chiefly by suture Excision resulted in a powerful, fully mobile and stable elbow capable of withstanding the heaviest strain in a shorter time than could be achieved by other methods Mr Wainwright considered excision to be the treatment of choice in all patients approaching middle age, whatever the size of the proximal fragment provided the coronoid process and the head of the radius were intact numbered and dated to permit subsequent inspection, and for periodic tests of efficiency with a sporing organism They do not consider colour changes in test capsules placed in the drums satisfactory, and think there is no substitute for careful bacteriological tests What is wanted, they say, is not so much improved apparatus as more rigid supervision of all the steps involved in the sterilising process Let us hope that hospitals will take this report to heart, but there will still remain the large quantity of cotton-wool used in doctors' surgeries and by laymen with little if any attempt at sterilisation The risks of this can only be removed by the manufacturers.

CHRONIC GASTRITIS

That chronic gastritis exists has long been recognised, but for many reasons it has proved extremely difficult to study Its clinical manifestations of nausea, flatulence, loss of appetite and vomiting may *be indistinguishable from the reflex effect of some* distant viscus, and little confidence can be placed in a diagnosis based on clinical grounds alone Indeed, until recently an easy diagnosis of gastritis, so difficult to disprove, has provided a cloak for ignorance all too convenient and some rebellious spirits have been induced to deny the existence of the condition at all Equally difficult has been the pathological approach to its investigation Post-mortem specimens of the stomach are damaged by autodigestion soon after death, and in cases of wasting illness shortly before death also **Faber** did much to overcome this difficulty by fixing the stomach in situ by direct injection of formalin immediately after death and in this way the reality of chronic gastritis was definitely established But since people do not die from chronic gastritis alone the correlation between the gastric pathology and clinical manifestations has remained obscure Moreover, **Faber**'s investigation was necessarily confined to the still picture of the morbid anatomy and histology of the specimen

The further elucidation of gastritis and its effects has recently been achieved by the application to the stomach of endoscopic methods of examination and the various stages of the disease process in life can now be observed in detail The endoscopic picture presents the characteristic changes of inflammation found in mucosal surfaces elsewhere Thus there are œdema, exudation, vascular congestion with petechial hæmorrhages, excessive secretion of mucus, and a hyperplastic or desquamative reaction in the epithelium These changes superimposed on the variable contour and rugosity of the gastric mucosa produce a remarkable variety of appearances **Hermon Taylor**[1] urges the importance of distinguishing between the true inflammatory effects and those due to the type of mucosa in the individual stomach This aspect is worthy of note, because there seems no doubt of the correctness of **Hurst**'s views on the congenital difference in the types of mucosa possessed by different individuals, whereby under-development or over-development of the rugosity can occur Lately **Miller**[2] has noted that the rugosity of the stomach arises only in the ninth fœtal month, and he observed a hypoplastic mucosa even in one mature infant It seems probable that there is an ætiological connexion between such developmental variations in the type of gastric mucosa and the incidence of gastritis Moreover, although not in itself a complaint with very disturbing symptoms, chronic gastritis may promote the onset of very serious illness Atrophic gastritis and depression of Castle's hæmopoietic factor with pernicious anæmia and subacute combined degeneration of the cord are an illustration of distant secondary lesions Locally, **Hurst** has shown that carcinoma of the stomach arises more frequently in patients with hypoplastic gastritis than in those with normal stomachs Peptic ulceration, too, can apparently be regarded simply as an extension of the disease process of hyperplastic gastritis, by the inflammatory depression of the resistance of the gastric mucosa to the digestive activity of its own juice Erosions, subacute or chronic ulcers may therefore follow according to the chronicity of the process and the intensity of the gastric acidity

Gastritis has been subdivided for classification according to the degree and profusion in which various changes present themselves to the gastroscopist Whether this is useful may be questioned, but the superficial catarrhal form appears to be distinguishable as a separate entity This condition is easy to comprehend for it occurs in people with chronic disease of the mouth, nose or respiratory tract, such as chronic sinusitis, tonsillitis, pyorrhœa, bronchiectasis and pulmonary tuberculosis The appearances are congestion of the tops of the rugæ, sticky adherent mucus and lumps of swallowed mucopus floating about in the gastric juice, all suggestive of simple secondary infection from above Peptic ulcers may be associated, but, like the diffuse changes, respond readily to treatment of the primary disease There seems to be, however, a more insidious form of gastritis indicated only by a diffuse and uniform œdema of the gastric mucosa together with some mammillation of the surface, due to true pathological hyperplasia as distinct from congenital redundancy of the rugæ This condition appears to be distinct from the catarrhal form of gastritis and no reasonable suggestions as to its cause have yet been put forward It may be a deficiency disease or due to hormone imbalance, or possibly an effect of the vagus Whichever may be the explanation, it is invariably associated with the more chronic and intractable forms of peptic ulceration **Bower**[3] has treated a series of cases of gastritis with vitamin-B complex under gastroscopic control The cases were all atrophic gastritis and a slight improvement was noticed in 2 out of 7, it is a pity that no cases of hyperplastic gastritis were included Until the cause of this œdematous hyperplastic form has been elucidated little progress can be expected in the reduction of the incidence of peptic ulceration It has been said that the diagnosis of gastritis can only properly be made by the gastroscope, for only by this means can the congestion, hæmorrhages and œdema be observed There seems to be little ground for the claim to make the diagnosis from a study of the barium-meal film or screen At most a relief film might show excess of secretion, but none of the essential minutiæ of a diffuse inflammation Much confusion has apparently resulted from descriptions of variations in rugosity as evidence not of the congenital type of mucosa but of gastritis Certainly, gastritis

[3] Bower, L L *Rev Gastroenterol* 1940, 2 313

Apparently it is the influenza virus itself which does the trick, centrifugation which can throw down the virus also deposits the agglutinating agent Moreover, treatment of infected fluids with excess of fowl cells absorbs out the greater part of the virus, which must therefore be presumed to act by virtue of adsorption on the red-cell surface

This finding is not a mere biological curiosity, for it may prove to have practical application in two directions HIRST succeeded on two occasions in recovering influenza virus from human throat washings by infecting chick embryos and proving that infection had occurred by the aid of the agglutination phenomenon If virus could be regularly recovered like this the necessity for using the ferret would be eliminated, but too much optimism would be unwise at this stage Thus BURNET[2] lately described a method for infecting chick embryos by the amniotic route with material of immediate human origin, but workers using it in this country[3] have not met with success comparable with BURNET's, and HIRST indicates that in his hands also the test has proved "rather uncertain" Far more hopeful is the finding that the agglutination phenomenon is inhibited in the presence of antiviral serum It is not yet known whether any viruses other than those of influenza can cause the phenomenon but it seems certain that the inhibition by immune serum is a specific effect Thus the immunologically distinct influenza viruses A and B, as well as that of swine influenza, can be sharply separated from one another by this simple in-vitro test, of which the results can be read in an hour or so The agglutination-inhibiting antibodies apparently parallel the virus-neutralising ones, as demonstrated by tests in mice, more closely than they do those concerned in complement fixation This is probably all to the good, for, though the matter is still in dispute, a majority of workers seem to attach more significance in influenza studies to measurement of neutralising antibodies than to the complement-fixation test, and in any case the vagaries of the latter test are responsible for more bad language than most pathological techniques If HIRST's results are confirmed—and they have been reproducible in at least two laboratories in this country—it may prove possible to diagnose influenza A or B (and perhaps C to Z if and when they are discovered) by comparing the agglutination-inhibiting titres of "acute" and convalescent serum samples, the only unusual reagents being washed fowl red cells and a supply of virus True, the diagnosis will be only available when the patient is already out of bed and will not help him much, but the new test may prove invaluable in epidemiological and other studies

MAKING COTTON-WOOL SAFE

PUERPERAL tetanus, though long recognised, is a very rare complication of childbirth The Registrar-General's figures for 1927–37 showed that one fatal case of tetanus occurred in every 700,000 deliveries, an incidence almost identical with that in the female population as a whole However, in view of PULVERTAFT's demonstration[4] that sanitary pads may be a rich source of both *Clostridium tetani* and *Cl welchii*, a committee under the chairmanship of Prof FLETCH SHAW was set up by the Royal College of Obstetrici and Gynæcologists at the request of the M O H the London County Council to consider the possibility of puerperal tetanus or *Cl welchii* infection arising from vulvar pads used in the puerperium, and to advise about ways of making non-infected pads and dressings available Their valuable report[5] is now issued In the maternity departments of a group of municipal hospitals and four voluntary ones they traced only one case of fatal tetanus in 244,562 deliveries, while data on puerperal infection with *Cl welchii* from one hospital where full bacteriological records were available showed 2 fatal and 35 non fatal infections among 704 cases of puerperal sepsis It should be pointed out, however, that *Cl welchii* may be present in the genital tract of puerperal cases without producing any clinical infection Both puerperal tetanus and gas-gangrenous infection more often follow abortion than full-time delivery, for which the greater chance of retained products to act as a suitable pabulum may be partly responsible That the risk may be specially grave in abortions therapeutically or criminally induced by the insertion of an unsterile cervical pack is exemplified by the extraordinary experience of BUSH,[6] of Texas, who in a fortnight saw 5 cases of post-abortal tetanus, all from the practice of one doctor to whom the women had gone to procure abortion All cases proved fatal despite intensive serotherapy

As regards *infection of dressings*, the committee confirmed earlier investigations that brown cotton wool, which is not submitted to any chemical treatment after it leaves the field where it is grown, is almost always heavily infected with spore-bearing anaerobes, including the tetanus and Welch bacilli White cotton-wool, which is boiled with strong alkali and then bleached with an oxidising agent, though not so heavily infected, is seldom free from anaerobes Here contamination was found to occur at the drying stage, when large volumes of hot air are blown over it Infection comes, then, from the air, the wool acting as an efficient filter Some change in the manufacturing process to avoid this gross contamination of a previously sterile substance is obviously desirable If this is impracticable the dried material should be resterilised before it is sent out Until one or other of these steps is taken the purchaser must himself see that the cotton-wool is sterilised before it is applied to an abraded surface Pyogenic cocci are easily killed, but the destruction of spore-bearing anaerobes in dressings can only be ensured by a rigid technique in the use of sterilising plant, and the committee has done well to detail the exact ritual to be observed in the use of hospital sterilisers There is an unfortunate tendency for the sterilisation of dressings to be left in the hands of a porter or nurse who does not fully appreciate the principles involved, and whose work is not supervised by one responsible person In some hospitals it seems to be no one's duty to reject a suspected batch The committee urge the need for loosely packed drums, for sterilisation at a pressure of 20 lb per sq in for 20 minutes after preliminary evacuation to a negative pressure of 15–20 in of mercury, for graphic records f the sulphonamide compounds, and it is reasonable to onclude that they were in fact due directly to the presence f phenobarbitone. At the same time it must be emembered that the patients who received treatment with the contaminated tablets of sulphathiazole were presumably seriously ill before the drug was administered, and it should not be too readily assumed that they would have survived if the treatment had been omitted. Chemical analysis showed that the composition of the more grossly contaminated tablets of Sulfathiazole-Winthrop appeared to be identical with that of Luminal-Winthrop. In other words, one of these sulphathiazole tablets was nothing more or less than an outsize tablet of phenobarbitone. Thus a patient who received 2 tablets of ‘sulphathiazole” was actually getting not less than 10 grains of phenobarbitone. The *J.A.M.A.* performs an essential public service by its warning of the potential dangers of the use of contaminated material. It points out that convincing evidence is not yet available to indicate clearly the casual relationship between the drug and the deaths that followed in time. It adds in all fairness a footnote recording that a coroner's jury of six physicians determined that the death of one patient could bear no relation to the possible ingestion of phenobarbitone. Nor have we yet heard what the drug manufacturers have to say. If we draw attention to the incident subject to all proper reservations, we shall inevitably raise at least two questions which deserve careful consideration. Is it in the interests of the community that the handling of potent drugs should be centralised? And if centralisation is desirable, is it not possible to check samples of every batch of drugs by chemical test before they are released? It is the general practice in the drug-manufacturing trade in this country to examine all the ingredients from which tablets are to be made and also to analyse samples drawn by the laboratory from all finished batches of tablets, the tablets not being packed until the laboratory has passed them both as regards identity and quantity of ingredients. It is also usual to draw occasional samples from the packed goods store, and submit these to the same tests again, and throughout manufacture and packing it is the custom to handle only one dangerous drug in one shop. Moreover it is the habit when contamination is reported for the manufacturers at once to recall all batches which may have been involved. If accidents still happen from time to time it is not for want of precautions.

VALUE OF THE MINIATURE RADIOGRAM

Most of those competent to judge now agree that in the miniature screen photograph we have a method of examination which is sufficiently cheap and labour saving to be applied to large numbers and sufficiently accurate to provide a sieve through which little of clinical importance will escape. This view is supported by a careful comparison of the findings of miniature and full-sized radiograms made by Clark, Poulsson and Gage,[1] which confirms previous studies.[2] A group of 1011 subjects, mainly Norwegian sailors, were photographed by both methods and the films were reported on separately by two radiologists. There was a very high correlation between the findings. The pathological changes overlooked in the miniature—such as small calcified foci and pleural thickenings—were all unimportant, whereas changes of clinical significance were always detected. In all, 55 “positive” findings were recorded in the 1011 subjects, 13 (1.3%) of them being definite lesions of active tuberculosis. There has been some misconception as to the precise functions of mass radiography and fears have been expressed lest healthy people be branded tuberculous on the slender evidence of a doubtful shadow on a screen photograph the size of a postage stamp. A positive finding on a miniature radiogram means one thing and one thing only: investigate. Full clinical and radiological investigation and sputum tests are required before an opinion can be given as to whether the shadow represents a lesion of importance and if so whether the lesion is due to active or arrested tuberculosis.

CONGENITAL DISLOCATION OF THE HIP

In studying the results of orthopædic treatment so often apparent only after many years, the cases re-examined after a set period must represent as large a proportion as possible of the primary material and measurable factors must form the basis of comparison. Severin[1] has tried to satisfy these conditions in a report on the treatment of congenital dislocation of the hip at the Stockholm Orthopædic Institute. He points out that in most of the large series previously reported only a fraction of the original cases had been followed up and that subjective findings or even the answers to questionnaires were accepted as standards of cure. This accounts for the great variance in the percentage of successes. Severin set out to survey the late results in cases where a satisfactory closed reduction by Lorenz's method had been initially achieved and re-examined all but 4 of 330 patients still alive 5–27 years after their reduction. This gave a total of 454 hips which could be accurately assigned to six groups on the radiographic findings, ranging from the almost-normal hip—for some tell-tale feature betrays even the best reduction—through subluxation to complete re-dislocation. This grouping was made more precise by correlation with the CE angle of Wiberg[2] which is the angle between the perpendicular through the centre of the femoral head and the line joining the centre of the head to the outer edge of the acetabular roof. Wiberg has shown this to be an accurate index of acetabular dysplasia and displacement of the femoral head in the adult and Severin established the normal values in children in order to apply it to his younger cases. On this radiographic basis only 4% were excellent results and 7% satisfactory, 43% were subluxated and in no less than 30% the femoral head was either in an extension of the true acetabulum or completely re-dislocated. The remainder showed dysplasia not amounting to subluxation. These rather gloomy findings were offset by the functional results, 25% being perfect and another 40% good, but good function associated with a poorly developed hip as shown radiographically tends to deteriorate and such joints are prone to degenerative arthritis at an early age.

Reference to the original radiograms showed that in 30% of the unilateral cases the presumably normal hip was either dysplastic or subluxated, the condition usually improving spontaneously while under observation; in the rest of the unilateral cases the sound side exhibited an uncertain CE angle. Thus it appears that both hips are nearly always affected to some extent by the congenital tendency to dislocation. Severin's results confirm that the prognosis, hip for hip, is worse in the bilateral cases, and demonstrate that the trauma of difficult reduction reduces the percentage of successes by more than half. It is this strikingly adverse influence of reduction-trauma on the late results that has led to modifications in treatment. It may be minimised by using a modified Lorenz method with only 70° of abduction, or, as in some centres in this country, by allowing gradual traction in an abduction-frame to replace manipulative reduction. Most satisfactory of course is diagnosis in Putti's “preluxation stage” during the first year, when simple abduction will effect a cure in 90% of cases. In such early diagnosis arthrography is most can only be confidently excluded by endoscopy, a point of some importance in the investigation of the large number of cases of dyspepsia now occurring in Service personnel So far the gastroscopic side of the examination of the Service cases does not seem to have been given the attention it deserves

The present treatment of gastritis is directed to the underlying cause in the superficial catarrhal type and to the complications such as ulceration in the diffuse type Direct treatment is difficult to institute in uncomplicated chronic gastritis, since the symptoms of gastritis proper are more easily borne than treatment by lavage Indirect measures taken to improve the general health, a bland diet with ample vitamins, and carminative or sedative drugs are of course useful The important thing, however, in the management of gastritis is to remember the increased tendency to serious complications and to ensure early investigation of any change in the symptoms Indeed, a case can be made out for regular radiological examination of all people known to suffer from diffuse gastritis

Annotations

SPIROCHÆTE IN STORED BLOOD

THE risk of transference of disease by blood-transfusion worries the layman much more than the physician But the risks are real if comparatively rare, and it is odd in view of present-day practice how little we have learned of the effects of refrigeration on infectious agents which may be present in donors' blood It is known that the malarial parasite may persist in the blood for many years after the patient has left a malarial district, and some authorities advise against using any person who has lived in a tropical or subtropical country as a donor But will the parasite survive in stored blood? Experience in recent years suggests that the virus of infectious jaundice may persist in serum for months, and Findlay[1] has recommended that donors, particularly of convalescent measles serum, should be kept under observation for a month after being bled to insure that they are not incubating jaundice The greatest fear, however, is of syphilis, and there are enough records to show that infection with *Treponema pallidum* may be transferred in blood-transfusion even from donors in the incubation stage of the disease It is customary at our many blood-depots, though not compulsory, to carry out serological tests for syphilis on the blood of donors, but a negative Wassermann or Kahn test, done even at the time of blood-letting, may mean no more than that resistance to syphilitic infection has not yet had time to develop Most blood for war-casualties is stored at temperatures of 3–5° C for varying periods before use and rather belated reports are now appearing on the effect of refrigeration on the spirochæte Harrison's well-known experiment of demonstrating motile spirochætes in chancre-fluid that had crossed the Atlantic four or five times showed that at ordinary atmospheric temperatures the parasite is remarkably resistant Bloch[2] has found that *Tr pallidum* derived from rabbit testicular emulsion and added to freshly drawn citrated rabbit blood did not survive longer than 3 days at a temperature of 3–5° C Even in 24 hours, the virulence of the spirochæte was apparently attenuated, there was now no motility and syphilomas did not develop in the rabbit testicle after injection of the blood spirochæte mixture until 48 days later compared with 22 days for the freshly prepared mixture Turner and Diseker,[3] using a smaller inoculum of *Tr pallidum* in human stored blood, found that spirochæte did not survive as long as 72 hours In storage in the blood-bank for a week is likely to be more reliable prophylactic against the transference of syphilis by transfusion than the performance of serological tests, though the routine use of these tests has an undoubted value in bringing to light unsuspected infections They also serve as a guide to the incidence of syphilitic disease in a community, and the figures obtained in various parts of the country might well be collected and made generally known

WHEN THE DISPENSER FAILS US

ONE of the many functions of the pharmacist is to act as a public watch-dog The final responsibility for dispensing drugs rests with him Should the doctor inadvertently prescribe a poisonous dose, the pharmacist who undertakes to make up the medicine shares the legal responsibility for any untoward consequences That the public weal has been so closely integrated with the pharmacist's self-interest is doubtless more than a happy coincidence, but it is certain that both considerations have played a part in achieving the high standard of pharmaceutical practice that now prevails in this country The present century, however, has seen the rapid growth of a new industry—that of the manufacturing pharmaceutical chemist—which has necessitated radical readjustments for the chemist behind the shop counter To an increasing extent he is becoming an intermediary between the manufacturer and packer on the one hand and the medical practitioner (or even the layman) on the other Such a development is bound, in the long run, to be inimical to the status of the pharmacist It may be argued that that is his affair, and that the doctor's primary consideration is that the drugs, accurately compounded, should always be available when required For many people, indeed, faith in the bottle is enhanced by a proprietary label, and external elegance counts for more than the pharmacist's art Admittedly modern methods of factory organisation and production tend to make for uniformity in the quality of pharmaceutical products, and so specialised is the work that opportunities for making mistakes are reduced almost to a vanishing point But it is rarely possible entirely to eliminate human intervention in manufacturing processes, and mistakes, though they are amazingly rare, are almost certain to occur from time to time When this happens the relative lethal power of the pharmacist compared with that of the manufacturing chemist is roughly represented by the homicidal prowess attributed to Saul and to David (I Samuel, xviii, 7)

On page 290 we report a case where a pharmacist, being out of stock of the sulphapyridine prescribed for a woman with pneumonia, and other shops being closed for bank holiday, dispensed sulphanilamide instead, without telling the doctor, thus robbing the patient, in the doctor's opinion, of a chance of cure A particularly unfortunate instance of a large scale calamity was briefly referred to by our American correspondent a few weeks ago[1] Since then, a comprehensive account of the affair has been given by Dr Morris Fishbein and his colleagues in the *Journal of the American Medical Association* for May 17 (p 2259) It is alleged that the Winthrop Chemical Company issued four lots of sulphathiazole tablets which contained varying amounts of phenobarbitone, and of the 56 people known to have received these tablets 9 died The toxic effects due to phenobarbitone ran true to type and included prolonged narcosis, incoordination, diplopia, emotional instability, anuria and skin eruptions One physician said that a man of 74 " went to sleep and never woke up " The ill effects recorded are quite unlike those which occasionally accompany the administration

ho work among the mentally defective The feeble nded and imbeciles of all grades are for the most part onest and conscientious beyond the ordinary When ey become delinquent it is nearly always as a result of uggestion from without

RELATIONSHIP OF EPIDEMIC AND ENDEMIC TYPHUS

ENDEMIC or murine typhus, transmitted from the rat to man by the flea *Xenopsylla cheopis*, does not as a rule occur epidemically and is a comparatively mild disease It is usually believed that exanthematic is derived from endemic typhus as the result of the rickettsias being repeatedly transmitted by the human body-louse instead of the rat flea Both strains of rickettsias produce a febrile reaction in the guineapig associated in the case of endemic strains with acute inflammation of the tunica vaginalis In man it has long been recognised that an attack of murine typhus immunises against exanthematic typhus, with the result that in North Africa various attempts have been made to use living murine typhus rickettsias for immunising the *indigenous* population against exanthematic typhus Nevertheless the exact relationship between endemic and exanthematic typhus has never been clear Fresh light has been shed on the problem by the *cross-immunisation* of guineapigs Earlier observers failed to show any great degree of protection against exanthematic typhus when killed murine typhus rickettsias were used as the immunising agents Thus Zinsser and Castaneda[1] reported that formalin-killed murine typhus rickettsias conferred a higher degree of protection against the homologous virus than against a strain of European typhus, only 30% of vaccinated animals resisted infection by the latter strain. Varela, Parada and Ramos[2] found that only 50% of similarly vaccinated animals withstood inoculation with Nicolle's Tunisian typhus virus Mooser and Sparrow[3] obtained absolutely no protection against heterologous strains The antigens used by these various workers were prepared from the peritoneal washings of benzol-treated typhus-infected rats Using a richer antigen and multiple injections Veintemillas[4] protected all his test animals against an epidemic strain of typhus isolated in Mexico It has however been *pointed out* by Castaneda and Silva[5] that in Mexico City some strains of virus appear to have properties which would place them as intermediate between the murine and the classical European strains

Within the last few years a number of methods have been introduced for producing large quantities of rickettsias *for use as antigens* Cox[6] has utilised the yolk-sac of the developing chick embryo, while Zinsser, Wei and Fitzpatrick[7] have employed a modified tissue-culture technique Durand and Giroud[8] have obtained antigens of the rickettsias of exanthematic and endemic typhus as well as of fievre boutonneuse and Rocky Mountain spotted fever from the lungs of mice inoculated intranasally with the rickettsias; a similar method has been used by Ruiz-Castaneda[9] using a Mexican orchitic strain injected intranasally into rats With this vaccine excellent protective results have been obtained against the homologous strain while observations now tend to show that protection may also be afforded against heterologous strains Thus Finlayson and Grobler[10] reported successful protection of guineapigs against infection by both endemic and epidemic rickettsias *obtained from South Africa* A single dose of 1 c cm was sufficient to protect against endemic strains but two such *doses were required* when epidemic strains were used to test immunity. Later Finlayson[11] found that *when the vaccine* was concentrated to half its original volume by precipitation with alum guineapigs were *protected against the epidemic strain* by a single 1 c cm dose Analogous results have been reported by Castaneda, guineapigs given three doses of 1 c cm of lung vaccine made from an endemic strain were immune to infection with a European epidemic strain those given two doses of 1 c cm were either completely or partially protected, while of 5 animals given one dose of 1 c cm only 2 showed partial protection The degree of immunity obviously depends on the amount of antigen injected It is extremely desirable that efforts should be made to determine the value of endemic murine rickettsias as an efficient immunising agent against exanthematic typhus in man

Human rickettsial diseases are now fortunately rare in these islands Exanthematic typhus however still occurs in Eire, while in 1938 Gray, Peters and Davies[12] recorded murine typhus from Bristol In this issue Ludlam Batchelor and Rhodes report what is apparently a case of tick-borne typhus in a Scottish port The source of infection was almost certainly ticks imported from South America Thus even in Great Britain interest in the rickettsias cannot be regarded as purely academic

EXTRA MILK FOR INVALIDS

THE Ministry of Food has now recognised the undesirability of telling the dairyman what the patient is suffering from before he releases an extra pint or two of milk for him Under an amended arrangement the practitioner need only certify that the patient for whom extra milk is medically desirable is suffering from a disease or condition specified in the First Schedule to the Sale of Milk (Restriction) Order '

Prof F R **FRASER**, who has for some time been acting in that capacity at the Ministry of Health, becomes director-general of the Emergency Medical Service on the retirement this month of Sir **JOHN HEBB** who combined the post with that of director-general of medical services at the Ministry of Pensions, where his services will remain available

A SPECIAL meeting of representatives of home divisions of the British Medical Association will be held at B M.A. House, on Thursday, Sept 11 at noon, and will continue on the following day.

THE medical as well as the pharmaceutical world will be the poorer for the rather sudden death at Bournemouth of Mr F. C **GOODALL**, for his journalism had a quality of its own. Always well-informed, often eloquent, his writing was apt to carry conviction to the most deeply opinionated. And so he may have contributed, more than we know or he would have dared to hope, to just pharmacy

THE INDEX and title-page to THE LANCET Vol I, 1941, which was completed with the issue of June 28 is now ready A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager, 7 Adam Street, Adelphi, W C.2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

MEDICAL CASUALTY —In a recent casualty list W S Captain H C A. Harris, M R C.S, is posted as wounded.

useful, as it is in studying the "healthy" side in unilateral cases and the stages of reduction and healing It is a simple and safe procedure, though an anæsthetic is needed for young children, and its popularity here is growing Severin uses per-abrodil diluted with an equal quantity of saline, 3 c cm being introduced into the joint through an anterior puncture, pictures must be taken rapidly because the medium is soon absorbed The results are not always easy to interpret without experience but are often so valuable that the method deserves wider use The arthrogram demonstrates the relation of the free fibro-cartilaginous edge of the acetabular roof, the limbus, to the femoral head—the key to diagnosis of dislocation It may indicate the probable failure of closed reduction if there is a long narrow capsular isthmus and thus save valuable months

Together with the minimising of trauma, the need for maintaining function at the hip from the earliest stage is nowadays more and more realised Severin leaves the knees out of the reduction-plaster, so that rotary movements of the femoral head may influence the development of the acetabulum, and Fairbank[3] has always insisted on the importance of early walking and crawling in the plaster Bauer,[4] too, has described how, after reduction in infancy, the child can walk later on in a simple abduction-brace It is evident that satisfactory closed reduction is only part of the solution to the problem of the congenital hip, diagnosis in the pre-ambulant stage, reduction with minimal trauma, and fixation allowing maximum function are also to be aimed at It is in helping to achieve the first of this triad that the arthrogram may prove of great value

SERUM TREATMENT OF PERITONITIS

SCANDINAVIAN surgeons have lately been employing serum in the treatment of acute peritonitis, especially of peritonitis complicating appendicitis, and some of them at any rate are enthusiastic about the results Bohmansson and Norup[5] of Orebro quote Swedish figures for general septic peritonitis, which in the decade 1929–39 show a fatality of 40–50%, whereas in the two years 1939–40, when serum in massive dosage has been given, the figure has dropped to just over 6% J Fog-Møller[6] of Kolding, Denmark, compares two parallel series Serum was given in 79 cases, with a fatality of 21 5%, no serum was given in 36 cases with a fatality of 40% On the average the patients who had serum were afebrile a fortnight sooner than the others, and stayed in hospital 13 days less The serum used contained antibodies to the two main types of organism that were considered pathognomonic—the different varieties of *Bacillus coli*, and *Clostridium welchii* This is referred to as "peritonitis serum" Dosage is all-important The only good results have been obtained with massive doses aimed at producing quick results In Orebro Hospital, in a first period in which no serum was used, the fatality was 42%, with small serum dosage it was 50%, in the third period, comprising the last two years, the dose was much increased and a fall to 6 3% was obtained During these same two years, however, sulphonamide drugs were used for the first time, and there must be much doubt about the relative contributions of serum and chemotherapy to the patients' recovery Bohmansson and Norup have definite ideas about what they expect from the combination of treatments The serum counteracts the toxin of the anaerobes and of the colon bacilli, while the sulphonamide attacks the actual bacilli (*B coli* and streptococci) and inhibits their growth Fog-Møller does not seem to have used chemotherapy, and his results, though good, are not so striking The dosage advised by Bohmansson and Norup has been raised even in the course of the last two years It is now c cm intraperitoneally and 40 c cm intravenously the time of operation, with smaller doses intramusc during the next few days They operate on all cases peritonitis that they consider fit to stand laparotomy. They remove the inflammatory exudate and any infected material, but do not wash out the peritone cavity They make a rule of closing the abdom without drainage, except where there is a localised ar of infection which obviously requires a drain They operate under spinal anæsthesia, counteracting fall o blood-pressure with intravenous fluids during operation The main points of their after-treatment are intravenou fluid, warmth to the abdomen, inhalations of oxyge and small repeated doses of morphia They allow no aperients, no enemata and no rectal wash outs As early as possible—usually about the second or third day—they get the patient up and let him sit on the closet and have his first motion naturally. Whatever its prime factor, their treatment seems to have been most successful in these last two years, and it is noteworthy that the cases quoted are of true septic infection, with purulent exudate or positive bacterial findings on culture

THE DEFECTIVE LEAVES SCHOOL

THE educable mental defective is more often than not a pleasant person, and when he leaves his special school his family are usually glad to have him at home After care and supervision are needed, however, because some families do not provide the ideal environment for a simple, often highly suggestible, character, because home circumstances which are favourable when the defective leaves school may deteriorate, and because the defective may be able to earn his living, and it is as well that someone should keep an eye on him to see that he is not exploited For forty years the Birmingham special schools aftercare committee have been performing these duties Their annual report is the third of a juvenile series, given in alternate years, and deals with pupils who left the city's special schools during 1939 and 1940 and who are therefore all under the age of 19 The committee's task, never easy, has been hampered by the blackout, by raids and evacuation, by transport problems and by the difficulty of tracing families who have been bombed out Sometimes a whole family has gone to work and left the defective to the care of neighbours, and it then becomes a problem in tact to make advice and guidance acceptable to the unofficial foster parent The large numbers of patients supervised—375 boys and 2 girls—have made the task a formidable one, and it is to the credit of the committee that only 19 of the boys and 32 of the girls have been lost sight of More than half the remainder are wage earners Of the 217 boys in work some are in factories and warehouses, others in engineering works (9 of these are skilled workmen), in electroplating and jewellery workshops, or in the building trade Others are doing outdoor work, serving in shops, o earning as wood-workers and cabinet-makers Of the 132 girls in paid employment many are in factories, few are in sewing trades or doing domestic work, three are skilled hands in engineering workshops, and 25 ar in press work In many cases the wages earned are good one boy of 18 earns 62*s* a week in a brickyard and thre girls earn 40*s* a week, the lowest wages are, among th boys 12*s* 2*d* a week, earned at filing, and among th girls 12*s* earned by greasing tins in a biscuit factory Only 7 of the 634 young people have been delinquent, of them being boys Five of the boys and the one gi were charged with stealing, the other boy with hou breaking It is noteworthy that whereas the incidenc of delinquency among young persons as a whole has risen in Birmingham during 1939–40, the incidence among th special school juveniles under aftercare has not changed there were only 7 cases in the previous two year period This is in keeping with the general experience of thos

nographs mostly aiming at economy in constituents hich are scarce or needed elsewhere Suitable drinking-ater may now be used instead of distilled water in eparing aquæ and infusions and surgical solution of lorinated soda and arachis instead of olive oil in rtain injections *Chloroform and alcohol now take the* ace of glycerin in elixir of cascara, glycerin of tannic id and syrup of wild cherry (which now contains accharin instead of sugar), and extra honey takes its lace in mel boracis Glycerin is omitted altogether om the compound tinctures of rhubarb and cardamoms, incture of ipecacuanha, and tannic-acid ointment

In England Now

A Running Commentary by Peripatetic Correspondents

A YEAR ago Professor Ryle wrote an article in THE LANCET called "Of Death and Dying" It was a scholarly production and might be summarised in a telegram "*Dying doesn't hurt don't be afraid death* is the end finality Ryle Reg Prof" When I read it I felt like an adolescent caught playing with children's toys, a grown boy who still believes in fairies and converses with animals, for I had always felt that the tiny speck of what we call life, emanating from that ever-changing mass of cells that is I, would go on even when those cells with one accord sought other frames or lay in dust content I never reasoned about it—it was as far beyond my control as the autonomic system—but I felt and still feel absolutely certain about it But regius professors are great men, they have in their memories a large number of the salient points of human knowledge, and that article, which was a snub to my and many other people's beliefs, made me retire to chew a reflective cud in statu humiliato I have chewed quite a bit in my spare time since then

Professor Ryle reminded me of a pike I used to know in London when I was a student, which requires some explaining You see it was my habit every day after leaving hospital to walk back to my digs in the East End I thoroughly enjoyed that, partly because there was always a feeling of release in the physical exercise, but chiefly because through one's mind ran a continuous stream of highly coloured and often very exciting pictures, which one could to a certain extent control I am sure that most young people are the same in this way, at any rate I have found throughout life that it is a great mistake to suppose one is different from anyone else except in very small ways, provided one's the same age, sex and race Well, one evening walking home I went down into a subterranean "Gentlemen Only" somewhere near King's Cross, and I noticed that high up in a big rather dirty, five-sided glass tank which intermittently filled with bubbly water was a small pike Some sporting lavatory man, I suppose, had brought it back from a day on the Lea Being a country lad I often used to make a detour on my way back and go and look at the lovely lines of that small pike It reminded me of the river at home, the greeny depths, the weedy smell, the entrancing blur of an open-eyed dive, the exciting glide of, say, a Red Palmer over a rising trout When I got up into the street again I often used to think What an unnatural environment, what can the poor beast think of it all? A few moments later I was striding up the hill towards the Angel, carrying on a conversation with a huge grim-looking pike "I'm King Luce" he says rather angrily with a swish of his tail, "the Terror of the Thames O yes! And all those poor fish who come in here, they come to worship me, of course Don't they cross their arms in front of them and bow their heads and pour out an oblation of water towards me?" "Yes, yes," I say nervously, for I'm about the size of a small roach "And what's more," King Luce continues, "God locks the *ones* that won't worship me up in those wooden boxes *and* fines them too" King Luce does an imperious swish round the pipe that runs through the middle of the tank and *comes* back to me "One fellow got shut up for an hour once," he says savagely, and does the round of *the* tank again When he was still again I ventured to ask him "Who is God?" "Who's God! What a ridiculous question Doesn't he carry a red and white chequered banner, doesn't he turn the sun off at night and on in the morning, *doesn't he* feed me, didn't he bring me here a long, long while ago when I had a terrible pain in my jaw, and make me a King Who's God indeed!" Then I'd try to explain to him our peculiar excretory system our lighting system, that lavatory men didn't really rank very high in our hierarchy but it was impossible He was *thinking in terms of dominance* over other creatures, of a peculiar bony, kicking distension of his stomach which only an alderman could appreciate, *of tactile sense along his lateral line* while I was thinking in terms of coloured pictures as seen by the limited human eye, and occasionally in heard-words, those rough signals between members of the same species There was no point of contact, and even if he had understood it would have seemed as fantastic to him as his fairly reasonable explanation which I have imagined may seem to you But suppose he was a regius professor pike what then? What would he make of all those people who line up below him especially when the pubs close? "Subjective phenomena, my dear boy" rejoins pike "entirely subjective" "But what of God with the chequered duster and his rows of boxes?" I ask "Projection figure, formed out of reflected shadows, that's all," says he "The world consists of this tank and I can see no evidence of anything outside it"

Now which of those two pike is nearer the mark? The fact is we haven't the slightest idea what life is It may be a state of matter like heat, or the result of an upset of some natural equilibrium like pâte de foie gras, or akin to the product of the symbiosis of a fungus and a mammal like the writings of D H Lawrence The vast probability is that we couldn't understand the truth and as for putting it into signals—into words—the impossibility of that seems to me one of the certainties Meanwhile my projected Heaven is the best that this male mammal has known in his present cellular state Location? English countryside, undoubtedly Mostly spring, say about May 7 But we'd better be able to switch on to other times if we want to Let's have a little bright October Righto I'll switch it on Companions? Most certainly It's that which makes a future life imperative I would rather not have lived at all than be severed for ever from some, and this seems to be the basic instinct in all creatures Whatever lies ahead of us I have a hunch it will have two paradoxical qualities because in every minor discovery I have made in my life in the natural world they have been present, it will be much simpler and at the same time much more wonderful than anything one could have imagined Like the youth of the Large Blue butterfly Childish? I wonder Is it as childish as the average human being's conception of time—as a stream as a linear thing marked out into reigns and centuries and eras, whereas it is so *obviously* an *endless circle* with repeated recombinations of life and matter? Yes I suppose we must have a hell Ten to one it's a city We'll do our slumming there We'll throw them picture books over the fence It may help them to get out, for they are self-immured "Entrapped behind a palisade of words, we shall be sorry for their littleness"

* * *

Medicine today more than *ever, seems to be always* working under pressure This is probably more apparent in a reception area, where hospital clinics seem to grow larger and larger One *gynæcological clinic* in this hospital establishes a new record for attendance about once a month, but certain psychological factors may account for this Certainly *the presence of* large numbers of fellow-sufferers seems to have a paralysing effect on the female sense of time The harassed gynæcologist after good-humouredly listening to the first three patients making futile calculations about the date of the last period, based on such premisses as "Well, it'll be a year ago come Michaelmas," or "The day Tommy got the measles which was either *last* Saturday, or the week before" took his fate in his hands and addressed the whole of his waiting suppliants There and then, he ordered they must get out pencil and paper and work it out in terms that could be more *easily recorded* The response was immediate and tremendous, and *far from* bringing blushes to their collective cheek, the whole clinic echoed with peals of laughter The histories taken from then on were prompt and business-like *Nevertheless* I often wonder what the reactions of a patient can be who,

MEDICINE AND THE LAW

A Pharmacist's Error of Judgment

THE new Pharmacy and Medicines Act entrusts to the Pharmaceutical Society the enforcement of sections 8 and 9, which prohibit advertisements of remedies for certain diseases or relating to abortion, and, after the end of June, 1942, section 10 which requires the disclosure of the composition of medicines The society, of course, already possessed disciplinary powers over its members by virtue of part 1 of the Pharmacy and Poisons Act, 1933 What seems to be the first of such cases against a member was inquired into by the statutory committee at a sitting at Derby on July 30 Complaint had been made to an insurance committee by a doctor that although he prescribed M & B 693 tablets for a patient suffering from lobar pneumonia the chemist supplied sulphanilamide tablets The prescription, dispensed on April 14 (Easter Monday), was a repeat of one dated April 11 (Good Friday) which was correctly complied with Since the discovery of M & B 693, the doctor said, he had not had a failure in a case of lobar pneumonia He was puzzled therefore in this instance when the expected response did not ensue, and this caused him to examine the tablets, which he found to be wrong The chemist informed him that, as he had not got the M & B 693 tablets, he decided to give the nearest thing to them as he understood matters The doctor replied that, if he had telephoned him he could have supplied the tablets he considered essential or the patient could have obtained them from another chemist The patient had died and he considered that her failure to obtain this essential specific drug had robbed her of a nearly certain chance of cure In a subsequent letter the doctor stated that the fact of the prescription being presented when other chemists' shops in the district were closed did not excuse the changing of it, but he thought this might be regarded as a somewhat extenuating factor The pharmacist explained that he believed the shop to be the only one in the area which was open on Easter Monday morning, he therefore felt obliged to dispense the prescription Owing to difficulties of transport and closing for the holidays (the main wholesaler was closed for ten days at Easter) no M & B 693 was in stock At the time he considered he was doing his best by substituting sulphanilamide; now, however, he fully realised his error

Major L E Simpson, presenting the case for the society, pointed out that, according to the statement upon matters of professional conduct prepared by the council, an offence was committed if there was a substitution of articles or ingredients, save in cases of obvious error or emergency, and in all such cases the authority of the physician should be obtained Here the defence did not suggest that there was obvious error or that the authority of the physicain was obtained The rule further required a note to be made in the prescription book of the alteration and the other things that constituted the emergency The only emergency which he could see in this case was that the drug was not in stock The doctor said that if he had been advised that it was impossible for the chemist to supply the drug he himself could have done so Major Simpson pointed out the importance of a doctor feeling sure that, in giving a prescription, he was saying the last word and that it would not be altered without reference to himself The society did not suggest that anything was done wilfully or with a malicious purpose The pharmacist agreed that he could have communicated by telephone with the doctor There was a rota of the local chemists for dispensing urgent medicines during holidays, but it did not apply on Easter Monday morning Asked whether his training enabled him to realise that there was a considerable difference between sulphanilamide tablets and M & B 693, he replied that he had not realised its full significance until this case came up

Delivering the decision of the committee, Mr G R Hill, the chairman, said it was common sense that, when a chemist was told to make up or supply a certain drug or medicine, he should implicitly follow the doctor's direction unless he suspected that a mistake had been made or there was some emergency which prevented him from doing so If he thought the doctor had some mistake, such as prescribing an excessive dose some poison, he would be justified in self-protec in not making up the medicine without communica with the doctor, but he ought to communicate with immediately In the case of drugs like these, q apart from the printed rule of conduct, it was the d of the chemist, if he had not got the particular tablets stock and could not get them elsewhere, either to up the doctor at once and ask whether he should su tute other tablets, or, if he thought that time was v important, to substitute the nearest thing he had, bu only on condition that he informed the doctor at th earliest possible moment that he had been compelled by force of circumstances to alter the prescription Otherwise the chemist would be taking upon himself to prescribe for a patient whom he had not seen and of whose condition his only knowledge was that a doctor who had seen the patient had prescribed something different from what the chemist was proposing to make up In the present case the pharmacist clearly made a very grave mistake It might be that if he had tried to ring up other shops he would have found them all closed on the Easter Monday and he could not have got the proper tablets It might be also that if he had tried to ring up the doctor he would have found that he was out on his rounds In those circumstances, if he really thought the other tablets were substantially the same, he would have been justified in supplying them, but only on condition that he got into touch with the doctor as soon as possible "I do not myself," the Chairman proceeded, "attach very much importance to the distinction between the two tablets What I attach importance to is implicit compliance with the doctor's directions" The chemist had admitted his mistake The committee, with considerable hesitation, had decided not to direct the removal of his name from the Register, but the chemist must understand the importance of obeying the rule

---

FOURTH ADDENDUM TO THE B P

A FAIRLY large addendum to the B P 1932 will come into force on Oct 1 It contains the following 26 new monographs

Benzyl benzoate, bismuth subgallate, digoxin, dilute ointment of mercury, ephedrine, exsiccated sodium sulphate, hamamelis ointment, injection of calcium gluconate, nikethamide (Coramine), procaine and adrenaline, quinine and urethane, and sodium morrhuate, light liquid paraffin, magnesium trisilicate, mandelic acid, morphine sulphate, nicotinic acid, pamaquin (Plasmoquine), phenyl mercuric nitrate, proflavine sulphate, sodium metabi sulphite, sodium morrhuate, solution of sodium hydroxide, sulphanilamide, suramin (Germanin, Bayer 205), and urethane

The inclusion of sulphanilamide marks the final absorption of chemotherapy into orthodox medicine. *Several of the monographs extend the process of estab*lishing official substitutes for drugs hitherto manufactured abroad, the proprietary names for these are shown in the above list in parentheses The new Ung hydrarg dil consists of the familiar Ung hydrarg (30% Hg) diluted with two parts of simple ointment, so that its strength will be 10% Hg, in future the dilute ointment will be dispensed when "mercurial ointment," "mercury ointment," or "blue ointment" is prescribed It will come as a surprise to some doctors to see that morphine sulphate was not in the B P before, but in fact only the tartrate and hydrochloride were included Paraff liq lev has a specific gravity at 15 5° C of 0 835–0 87, compared with the 0 88–0 895 of Paraff liq B P We are also told the "kinematic viscosity" of the light paraffin, which is to be not greater than 33 1 centistoke at 37 8° C Hitherto viscosity of liquid paraffin has been expressed in terms of rate of flow through a Redwood viscometer, and the methods now laid down for estimating and expressing viscosity are set out in an appendix Another appendix describes the methods of sterilising and dispensing solutions for parenteral injection

The addendum also contains the amendments already made official by announcements in the press in February covering the use of Indian squill and Indian valerian and there are a number of emendations to existing

Letters to the Editor

EATMENT OF SOLDIERS AT CIVILIAN V D CLINICS

ir,—Owing to the fact that it is Army policy to treat liers suffering from V D as inpatients so long as they contagious, all that civilian clinics were asked to do s to carry out *preliminary* tests of cure for gonorrhœa l *routine* continuation treatment of syphilis, definite ndards being laid down for each The advantage of s course is that it saves a considerable amount of time l transport Practically every civilian clinic accepted s proposal

Every soldier attending a civilian clinic should take h him a pro forma On this the medical officer erring the case should set out the patient's name, &c , ease, treatment or examination required (subject to y contra-indications such as signs of intolerance), ults of previous examinations with dates, summary previous treatment with dates, and other observations is should give the medical officer of the clinic all the formation necessary It is to be regretted that this o forma is not always correctly filled up, but medical en are notoriously bad at filling up forms and the large ajority of Army M O s of today are the G P s of yesterly, so that too much blame must not be cast on the my The Army M O has much to learn when he st enters the Service and one cannot be surprised if a w M O makes mistakes in the multiplicity of forms hich he has to complete

To reply to some of the points raised

1 The soldier cannot be expected to keep a V44 , he has ute as much kit as he can cope with already It must be membered that he does not live under the same conditions the civilian.

2 It is forbidden to prescribe sulphapyridine for a suspected se of gonorrhœa until microscopical examination has been rried out

3 A case which attends a civilian clinic for one or more eeks and then ceases does not necessarily, or even commonly, default " Soldiers are constantly being moved and there e many other reasons for non attendance—e g , operational responsibility rests on a civilian clinic if a man does not tend For a variety of reasons in war time it is impossible notify civilian clinics when a man is moved , this will be vious to anyone who gives the matter a second thought

If Dr White and Dr Erskine would realise that the ldier is comparable rather with the merchant seaman, ho goes from port to port, than with the comparatively atic civilian they would understand that their suggesons, though admirable in theory, are unworkable in actice

T E OSMOND,
War Office. Adviser in Venereal Disease

SIR,—Dr H H White and Dr David Erskine emphasise me of the difficulties experienced in the treatment service V D cases in civilian clinics In addition we ave suffered from overcrowding of certain sessions, with nsequent prejudice to the civilian patients, due to the ct that the civilian clinic has no power to control the mes of attendance of Service personnel The Ministry Health recently introduced in circular 2226 a scheme nsidered adequate for the diagnosis and treatment by eneral practitioners—under the general supervision f the local authority V D officer—of civilians in many reas The application of a similar scheme to the Serices, supervised by the Service V D specialists and arried out by the unit medical officers, should not be npossible, should make for continuity of treatment, nd would relieve the civilian clinics of any possible lame for unsatisfactory results as well as obviate ossible future difficulties consequent on staff problems nd the slowly increasing incidence of infections

Newcastle on Tyne A E W MCLACHLAN

ACUTE ULCERATIVE STOMATITIS

SIR,—I have read with interest the article by Colonel Valton and his associates on the treatment of three cases f acute ulcerative stomatitis by blood-transfusions, for luring the past year I have seen more than 450 cases of ulcerative gingivo-stomatitis and have treated nearly 300 The severe illness and prostration described by Walton and the presence of pneumococcus-like, rather than fuso-spirochætal, micro-organisms are perhaps the most unusual features of their cases I have examined more than 2000 direct films from ulcerative mouth lesions and have on occasions noted relatively large numbers of gram-positive diplococci which do have the morphological characteristics of pneumococci The suggestion by Dr Britton that they probably belong to the streptococcus group is interesting in view of the almost constant presence of coccal organisms in lesions of so-called Vincent's disease Indeed, the comparatively superficial nature of the ulcerations, the extremely strict anaerobic requirements of fusiform bacilli and Vincent's spirochætes and other considerations strongly indicate that invasion of the tissues by the latter association of micro-organisms is probably a secondary result of tissue injury by other means As Walton and his colleagues indicate, ulcerations of the mouth may depend on defective cell metabolism associated with deficiency of nicotinic acid (and possibly other components of the vitamin-B complex), regardless to some extent of the type of micro-organisms, or association of micro-organisms, found in the lesions when developed In about 10% of my cases typical fœtor has been absent

Mechanical trauma in the mouth, as a result of tartar, food debris in gum pockets, cervical caries and fillings, ill-fitting dental appliances, &c , should not, however, be forgotten I believe that nutritional deficiency and traumatic injury of the gums are the main ætiological factors in the disease This belief is based on the treatment of 276 cases of ulcerative gingivo-stomatitis since June, 1940—81 with nicotinic acid alone , 121 with nicotinic acid supplemented by local measures , 14 with ascorbic acid (with little or no beneficial effect) , and 60 by local treatment alone Successful treatment to some extent depends on the type of case—acute, subacute or " flaring " subacute. The last two types often respond only slowly to nicotinic acid or to local measures separately. Up to the present I have found the following method the most reliable —

(*a*) Nicotinic acid, 150 mg daily for seven days, followed by a maintenance dosage of 100 mg daily

(*b*) Chromic acid (10%) plus hydrogen peroxide applied to lesions on two consecutive days, with scaling of teeth on second day.

(*c*) Hydrogen peroxide syringing on third and fourth days

(*d*) Hydrogen peroxide mouth washes for seven days , removal of chronic traumatic foci (by tooth extraction, gingivectomy, &c) after (*b*)

By these means clinical ulceration is eliminated in approximately two days in the majority of cases, even when the ulceration is fairly widespread No relapses—so common after local treatment alone—have so far been encountered A detailed report of this work is now being prepared for publication as a sequel to my article in your columns (*Lancet*, 1940, 2, 32)

As Colonel Walton and his colleagues remark the cure of their cases by blood-transfusions may have been due to correction of a nicotinic-acid deficiency and my experiences perhaps give the suggestion some support Other components of the vitamin-B complex, and perhaps vitamin A, mentioned in connexion with the " sore mouth," cheilosis, angular stomatitis, perleche, &c of the Indian, Malayan, Egyptian and African investigators, may also be concerned

I am indebted to the Director, Army Dental Services, for permission to refer to the cases mentioned.

MODIFIED INSULIN THERAPY IN WAR NEUROSES

SIR,—The account given by Dr Sargant and Dr Craske of a " modified " insulin treatment and of their efforts to effect a reduction in the amounts of sugar and insulin used is of interest to all those practising insulin treatment It occurs to us, however, that in those patients who receive " just insufficient insulin to produce light coma, or even hypoglycæmic excitement," it would be enough to give potatoes only, without any coming up apprehensively for the first time is bustled about and has needles stuck into her with cheerful nonchalance Perhaps I am interested because my first term as a medical student was, owing to a certain rashness in disputing a right of way with a lorry when only mounted on a bicycle myself spent in studying medicine from the patient's point of view My first reaction, in a postconcussive state, was one of cheerful cooperation, when I had two teams, one attempting under local anæsthesia to set a somewhat fractured tibia and fibula, and the other to remove a well-fragmented windscreen from my scalp This attitude was, however, considerably modified when I finally came to my senses after a period of secondary shock Then I must confess the atmosphere of secrecy about the next move (particularly being forbidden breakfast without being given a reason) had an awe-inspiring, if not actually fear-generating, result A little explanation would go far to alleviate a lot of the anxiety provoked by the unknown in patients More than anything I learnt to appreciate the value of a basal anæsthetic which averted the horror of an ether induction, intravenous anæsthetics were really great fun but gas and oxygen was the only one after which I was immediately able to eat a big meal with a good appetite, so naturally it was a firm favourite I am sure that getting patients to take a cooperative interest in their treatment is well worth the extra trouble it involves and saves time in the end, but it is just these human touches that are first to be sacrificed in a rush

* * *

Three weeks ago I was called to see an A F S man who was in charge of a "knot and tie" section, he was complaining of numbness in his hands and feet and a discomfort in his lower back His knee-jerks were sluggish and his ankle-jerks were absent I asked myself Halliday's famous questions—why he took ill *how* he did, and why he took ill *when* he did I elicited this story A fortnight previously a man in his section had fallen from a rope and fractured his spine The knots in the rope were shown to be faulty and they had been tied by my patient He made a report to the chief which had been considered inadequate and he was required to attend before the committee to make his explanations in person This he did, but he had not yet been told of the committee's decision On the morning the committee met he was first aware of the numbness in his hands and feet and the discomfort in his back Here then were the answers to Halliday's questions, here plainly to be seen were the marks of his guilt Here were the hands and feet that slipped and the back that was broken as clearly imprinted as were the stigmata of the medieval saints The clinical diagnosis, however, was polyneuritis, and he died in a fortnight of respiratory failure Is there a gap here to be bridged? Do disordered psychological states prepare the neurological soil for the invasion of a virus? I offer this case to any outraged psychiatrist who requires a text for a lecture directed to Group-Captain Symonds and entitled "The psychiatric approach to neurology"

* * *

Not least among the difficulties of a patient at hospital is the trouble of fitting the right denomination to the right person It is the misfortune of women doctors that they have to exert their authority under the title of "nurse" or perhaps if they look very dignified, "sister," while the most junior male student will get called "doctor" Most of us appreciate this as a first glimpse of a future life when we will no longer fill the rôle of the lowest form of animal life, and if taxed for a decision one can always gently sidestep On other occasions it can be embarrassing Just before the war, students from the Welsh and English universities used to help in the organisation of camps in South Wales for unemployed miners We worked hard in a domestic way and there was a wonderful sense of fellowship When, however, it was discovered that you were a medical student your status changed quite a bit, particularly if you were the senior one present, for your juniors applying their well-practised technique, put it all on to you As the nearest doctor was some miles away, one couldn't follow one's instincts and put it all on him But there was a good medicine chest and once you had some confidence you could get on all right The scurviest trick of all, however, was played in name of democracy by the simple process of it was decided that the "medical officer" should sole charge of sanitation So there was no alt than to put into unwilling practice the principle doctors should concern themselves more closely public health I may say that principle triumphed, I dug pits, emptied buckets, and disinfected seats such vigour that I was promised that when South W had a Soviet I should be appointed People's C for Chemical Closet Control

One of my colleagues gained immortality by a diagnosis An Irishman came to him complaining that he was too ill to work "The trouble is, doctor," he said in a brogue which I cannot transcribe, "that my heart's in old Ireland" "On the contrary," replied his medical adviser, "your trouble is that your bowels aren't in the Free State"

SALARIES FOR NURSES

WHEN the Minister of Health announced the new rates of pay for the Civil Nursing Reserve in April[1] he also asked hospital authorities to review the salaries they were paying their nursing staffs But he realised that a revision of nursing salaries, however desirable, would add a heavy burden to hospital finances at a difficult time, and after negotiations with the British Hospitals Association, the King Edward Hospital Fund and the Nuffield Trust he has agreed to give the hospitals provisional help until he receives the report of a national committee on nursing salaries which he is setting up The scheme will be administered by the B H A which has drawn up the following minimal annual scale of nursing salaries

	£
Probationer	
1st year	30
2nd ,,	35
3rd ,,	40
4th ,, (until state-registered)	50
4th ,, (state registered)	70
State registered staff nurse	90

Voluntary hospitals which raise their nurses' salaries from Aug 1 or which had already done so since the minister's announcement, will be eligible for a grant for each probationer and state-registered nurse they employ To qualify for the grant the salaries must be raised to at least the minimal scale and the minister will also pay a proportion of the cost to the hospital of raising the salaries up to

	£
Probationer	
1st year	40
2nd ,,	45
3rd ,,	50
State registered staff nurse	95

The average cost to the hospital of these increases will probably work out at about £10 a year for each probationer, and £22 (including superannuation) for each state-registered staff nurse The increase in the expense will of course depend on the salaries the hospital had been in the habit of paying and in order not to give unfair advantage to those which have been paying the smallest salaries the grant will be limited to half the average increase—i e £5 or £11—or half the actual total increase whichever is less Rises for the junior staff will entail rises for the senior staff as well, and the grant of £11 for the trained nurse will also hold good for those in senior positions such as sisters, assistant matrons, and matron Midwives are to be dealt with separately

The national committee on nursing which is to be set up will consist of two panels, representing employers and employees The B H A as well as the King Edward Fund and the Nuffield Trust will be represented on the employers' panel

---

[1] *Lancet* 1941, 1, 495

SCHERING products have long been known in this country for quality and the new organisation advertised in the press assures continuity of supply since, as present stocks become exhausted, the preparations will be of entirely British manufacture The new research laboratories will be under the direction of Mr D H Hey, D Sc, lecturer in organic chemistry at the Imperial College of Science and Technology reach the second class from the top in school previous 'nervous breakdown," suicidal attempts, member of the family treated in mental hospital or committed suicide repeated court convictions, previous discharge from the Army, Air Force or Navy severe head injury, chronic pain or severe headaches, faints or collapses, fits or convulsions severe fears or nightmares, stammering, enuresis after 5 years recurrent diarrhœa or indigestion, dieting over a long period cramps spasms or tics, long litigation after an accident and doubt concerning conscientious objection Had such pointers suggested to the medical board that a psychiatric opinion might be helpful and had the psychiatric opinion been acted on, much time and trouble would have been saved , 75% of these men had been in the army considerably over three months and 25% considerably over one year Of 50 outpatients found to be so chronically ill that discharge was advised without treatment in hospital 49 could have been detected on intake by similar criteria

We also examined the histories of a sample (150) who were sent back to duty after treatment in hospital, and found that examination on intake would have elicited about half as many pointers to further psychiatric examination In these cases the pointers would not have indicated to psychiatrists such serious previous illness that the patients would have been rejected In other words early neurosis was less frequent, milder and of shorter duration

It may be said that medical boards have not the time to elicit indications of previous psychiatric problems according such hints as we have given Nevertheless the suggestions made for questioning entrants to the A.T C (*Brit med J* Suppl May 17, 1941, p 67) appear to us too meagre It was only suggested that a history of sleep-walking, bed-wetting fits and convulsions be asked for The following questions seem the easiest to ask and the most useful What class were you in when you left school ? What was the top class ? Were you ever knocked out by an accident or a blow ? Have you ever had a fit or a convulsion ? Have you ever fainted or collapsed ? Have you ever had bad fears ? Have you ever had bad aches or pains for a long time ? Have you ever been discharged from the Army, the Air Force or the Navy ?

CARE FOR HOME GUARD CASUALTIES

Sir —The letters that have appeared in your columns have mainly dealt with equipment and establishment of collecting posts where Home Guard casualties can be maintained until they are moved to hospital by A R P ambulance These posts must of necessity, be at some distance from battle stations, and, as attack may come from any direction, Home Guards may be cut off from collecting posts for a considerable time They must therefore be prepared to carry out efficient, if elementary, first-aid and tend casualties for hours if need be, until men can be spared to carry them to a post To meet this contingency first-aid instruction has been given to the men, but owing to lack of material this is as much use to them as a locomotive would be for their transport were no rails provided In your leading article of Aug 16 you say "The Government provides for each post" (i e platoon of 80 or more men) "52 pad and bandage dressings, 2 small tubes of tannic-acid jelly, 2 triangular bandages and a set of splints of which the longest is 17½ in This supply is intended for the most elementary first-aid treatment " Obviously the splints would only provide the most elementary first-aid for arm fractures, but even the most complaisant leader writer should be startled by the practical uselessness of splints without means for attaching them to a limb Splints can readily be improvised whereas means of attachment are difficult to procure offhand To use strips of clothing for this purpose is a needless extravagance Triangular bandages are cheap and efficient, they can be washed after use and reissued , moreover, they exist in huge quantity in the B R C and A R P stores and dressing stations where they are virtually "frozen" Their actual point of usefulness is not central, in store but peripheral, where casualties are sustained and first-aid is required A redistribution of existing supplies is necessary, together with a scheme for replacement of used bandages, their laundering and recirculation

Morphine antitetanus serum sterile vaselined gauze and sulphanilamide dusting powder must also be available and as casualties may have to be kept for hours perhaps days, medical comforts (cafe au lait cocoa and milk sweetened condensed milk in small tins) should be provided at section and casualty collecting posts

To expect the Home Guard to provide its own casualty equipment is inappropriate, to say the least and you betray your estimate of our great nation s attitude to, and recognition of, the gratuitous services and sacrifices by the Home Guard for national preservation when you write that a medical officer "can only tap these supplies if he first collects funds, and this is a duty which may well fall to his lot" Is it meet that the M O procure a hurdy-gurdy suitably inscribed and tour his battalion area or badger already overburdened people to shoulder yet another burden and subscribe to his first-aid fund ? We have come to a sorry pass when a medical officer must turn beggarman Can the *Lancet* really endorse such a policy ? Provision for Home Guard casualties is a national duty which cannot be fobbed on to the charitable nor can it be left in its present impossible state While the Home Guard is willing to face the risks of modern war it cannot be expected to provide its own first-aid material or to squander life and limb needlessly for lack of it The problems of medical equipment and organisation in the Home Guard are specific and simple and since all necessary supplies will be of use in civilian life after the war there can be no inhibition to their provision on grounds of economy, or for that matter on any other grounds

London, W 1

W G Macdonald

Sir,—The Good Book says "without vision the people perish" Therefore, those of us who remember multiple medical muddles will take little comfort from the letter of your anonymous H G M O , who Jove-like assumes that "the C -in-C 's intention as regards the function of the Home Guard can be roughly assessed by the quantity of the equipment issued to them," the corollary being that since their medical equipment is nil his intentions are nil, and therefore their function is nil—surely a somewhat risky statement even under the guise of anonymity

Marlborough laid it down that no action and no campaign could be won without application of the three I's, industry, intelligence and imagination, and that the greatest of these was imagination Does H G M O really believe that we should only follow the instructions laid down in A C I 468 and 752 of 1941 (unless, of course they are instantly amended) ? Does he realise as a professional man the enormity of no splints longer than 17 inches, no morphia, no Dettol, no sulphanilamide, no antitetanic serum, no antiburn or gas equipment, and still think that all's well and can be left to that deus ex machina, the R A M C , "who within twenty-four hours" are to be conjured out of the sky to deal with casualties anywhere and everywhere from Dover to the Great Green Belt and upwards to John o' Groats ? Can he not visualise desperate fighting in the open against vast air- and sea-borne enemy hordes What authority has he to assume that this tactical medical problem without parallel can be mastered in a day by the R A M C , who like the Home Guard are meagrely equipped for field casualties Indeed he is one of great faith, though perhaps of little experience of such debacles as the retreats from Mons and Cambrai

I note his paternal advice to follow the instructions laid down by the War Office to train stretcher bearers In what ? Lifting stretchers ? for there is nothing else with which to wet their curiosity or grey matter Again he adjures us in the midst of battle, when cut off from the beloved A R P , to organise aid-posts but he does not tell us what magic wand to wave in order to stock such posts with the very minimum medical requirements mentioned though I see he states that we are to have a system of runners to bring first-aid equipment across field or fen, by day or night, without any knowledge of the whereabouts of the post or the enemy To my mind his attitude savours too much of gregarious and dangerous complacency

Harley Street W 1

V. B Green-Armytage

sugar, to restore the blood-sugar to normal values In this way a complete sugar economy would be effected, apart of course from the occurrence of those complications for which Sargant and Craske have been at pains to provide Almost a year ago (*Brit med J* 1940, 2, 310) we published a method of carrying out insulin treatment under war-time conditions in which potatoes were used as a substitute for sugar In this method 7 g of glucose are given intravenously to terminate the coma The patients wake up from the deepest coma within two or three minutes and are ready to drink potato soup, of which 12–18 oz is given This is followed by tea or cocoa and biscuits or bread and butter In this way no patient receives more than his sugar ration in the week We were also able to show that by administering the insulin intravenously it is possible to reduce the amount required to induce coma and incidentally to avoid the onset of such complications as delayed recovery and late shock so much feared by your contributors

JAMES S McGREGOR,

CALCIUM AND PHOSPHORUS STUDIES IN NORMAL PEOPLE

SIR,—Dr Harris's letter of Aug 23 contains many wrong and inaccurate statements

Calcium content of the tissues —There is a large literature on this subject, including work by Weiske, Voit, Aron, Sebauer, Kost, Patterson, Denis, Minot, Clark, Heubner, Rona and Corley As much calcium by injection as 1 2 g per kg over short periods and 0 7 g per kg over prolonged periods have been given All are agreed that the calcium content of the tissues (e g , heart, blood-vessels, brain, muscles, abdominal organs, &c) does not rise above normal When Dr Harris raises the bogy of " calcium saturation " with its dangers, and uses such phrases as " tissues contain more calcium under a large intake," he is talking nonsense

Advantages of a high calcium intake —When Dr Harris writes " no data are available to judge which (intake) is the best," he displays ignorance Among others, work on this subject has been done by Sherman, Campbell, McLeod, Booher, Bessey, Toepfer, Gaunt, Irving and Thomson All are agreed that in contrast with a low calcium intake an optimal or high calcium intake produces more rapid growth, more efficient growth, earlier maturity, longer duration of reproductive and ordinary life, greater success in rearing young and better growth of young It should not be difficult for Dr Harris to answer his own question " Which of the two conditions is more desirable ? "

Renal excretion of calcium —On a low calcium intake the daily excretion of calcium in the urine is about 0 06 g and in the fæces about 0 2 g When the intake of calcium is high, normally only a small amount of the added calcium is excreted by the kidney The amount of increased work this gives to the kidney is insignificant , exactly how little has already been explained to Dr Harris by Dr McCance and Dr Leitch

Detection of calcium insufficiency —If large sections of our population are ingesting less calcium than is necessary for equilibrium between intake and output, then they are getting insufficient calcium That is simply a matter of logic, for the healthy body must retain some of that mineral The above has been shown by dietary surveys, among others by Orr, Corry Mann, Leighton, Clark, Davidson, McGonigle, Crawford, Broadley and Potts But Dr Harris asks for signs of calcium insufficiency Clearly osteoporosis is the terminal stage like the coma of diabetes But demineralisation of the skeleton can take place without X rays being able to detect it Thus in thyrotoxicosis, which is associated with an excessive calcium loss from the body, Golden and Abbot could only detect the decalcification in 22% of cases despite the employment of radiographic controls The conclusion is not that in 78% of thyrotoxicosis there is no demineralisation but that X rays are not sufficiently sensitive

There is a means of showing calcium insufficiency by employing calcium balances Above an intake of 1 g calcium daily, in the normal healthy subject, no more retention of calcium occurs If the body stores more calcium at intakes above 1 g than at 1 g , then there is calcium insufficiency Dr Harris himself has provided us with such a series of cases from Liverpool, thereby proving the people he considered normal were actually calcium deficient At an intake of 0 8 g calcium his subjects stored 0 269 g calcium As the intake increased to 1 791, 1 99, 2 566, and 2 712 his stored more and more calcium, until at an intake of 2 71 stored as much as 1 980 g and these figures are averages That is evidence there was calcium i present and Dr Harris thought they were normal Dr must now know how very hard it can be clinically to certain there is no calcium deficiency in the adult pop

Calcium retention in middle age —Dr Harris has " great retention of calcium is a peculiarity of middle It really does not matter whether this was stated in a in a letter In table VI of my first paper I compared calcium metabolism of old and young adults and found th similar The statement by Dr Harris is therefore wr When Dr Harris writes " Obviously in the fully cases the middle aged cannot react differently from young To demonstrate his point the subject of Robertso table should have been kept in a calcium unsaturated state he begs the question Let me put it very simply There difference in the storage of calcium in old and young adult Large retention of calcium in adults is a sign the body is calcium deficient and this obviously can occur at an There is nothing peculiar about this

Osteoporosis and vitamin D —When Dr Harris writes " very rare condition of osteoporosis is now considered to be du to vitamin D," he is again inaccurate In thyrotoxicosis and hyperparathyroidism the osteoporosis is not due to vitamin deficiency , the former is due to thyroid activity and the latte to parathyroid activity When the intake of calcium fall below equilibrium level the demineralisation of appa normal people is due simply to lack of calcium and not to vitamin-D deficiency As Sherman says, the factor of prime importance to the optimal storage of calcium in the body is the presence of a sufficiently liberal allowance of calcium (optimal) in the food Vitamin D without that optimal amount of calcium cannot do its vitamin storage work properly There is also a wide literature on this subject including work by Aub, Cameron, Fraser, Tibbits, McLean, Stettner, Hunter, Barr and Bulger

I have written at length because it is clear that Dr Harris is deceiving himself (and might deceive others) through his inadequate knowledge and grasp of the relevant literature Dr Harris's conclusions and results on calcium are at complete variance with those of 39 workers I have limited myself to quoting Their observations are all consistent with one another and are now generally accepted Their findings must be proved wrong and Dr Harris's calcium work confirmed before hi unorthodox views can be considered

London, W 1 J DOUGLAS ROBERTSON

MARTIAL MISFITS

SIR,—Writing about Service misfits (May 17, 1941, p 633) you stated that passing men who are grossly neurotic or feebleminded meant expense, delay and waste, and further that the medical boards of the Ministry of Labour have seldom called for a psychiatric opinion In a later leader (July 26, p 103) you reported that a third of the American rejections were made on psychiatric grounds and that this third represented 5% of the examinees In a certain region the medical director of the examining board had quashed the psychiatrists' opinion in two-thirds of the cases In other words the medical director sent into a unit of 5000 men 150 about whom the psychiatrists had given a poor prognosis

There are other facts related to this problem which should be mentioned Baillie reported (*Amer J Psychiat* January, 1941, p 753) that of 200 admissions to a Canadian Army neurological and psychiatric unit 144 were discharged from the army Of the 144, 47% should have been rejected at intake and 41% detected because they presented severe psychiatric problems during their preliminary training Baillie concludes that 88% of the discharges would have been rejected had adequate psychiatric examination been made at intake or shortly after We have tried to decide how our experience compares with Baillie's

Of a random sample of men (200) whose discharge was advised after treatment in a psychiatric unit, about 70%, in our opinion, would have been rejected on intake had attention been paid to indications of previous neurosis or psychosis The evidence of previous severe psychiatric problems was indicated by such pointers in the history as illiteracy, attendance at special classes, inability to

Obituary

ALFRED JOSEPH CLARK

M C, M D CAMB F R C P, F R S

THE brief biographical sketch of Prof A J Clark in ur Scottish letter of Aug 9 has been followed by personal ppreciations of a singularly convincing character Since he end of the last war Clark held in succession the chair f pharmacology at Cape Town, at University College, London, where he was for a time dean of the medical faculty, and finally at Edinburgh It was indicative of his character that his colleagues (in the words of one of them) and students always spoke of him with affection The reason was not far to seek, for he had an intense interest in his fellow creatures A staunch friend with a generous spirit his advice was sought by many with the knowledge that they would receive of their best, and he had a happy way of putting juniors at their ease by giving them the impression that what they had to say was entirely new to him At work or at play Clark was whole-hearted in action He infected with his enthusiasm his comrades in research or teaching and he could hold his own with juniors at fives or squash rackets At the outbreak of war he took charge of the A R P for the safety of students and laboratories around the Edinburgh medical quad, taking more than his share in the filling and stacking of sandbags Time will not erase the memory of the upright igure walking rapidly across the quad with hands behind is back his cheery morning greeting and the luncheon our talks at the Union where his erudition astonished ot only his colleagues in medicine but those from other aculties

Lafayette

A survey of his published work shows the thoroughness f A J Clark's early grounding in the basic sciences xperimental physiology provided his approach to harmacology but throughout his career Clark always rought to his researches a freshness of outlook that pened up new possibilities for investigations in many irections The extreme care with which he prepared imself for exploring the pharmacological aspects of a ubject is illustrated by his "Comparative Physiology f the Heart" published in 1927, which contains original bservations on the vertebrate heart, representing many ears of patient study Nor did he ever show any endency to become stabilised within the limits of some pecialty As a result of his early experience—which ight almost be taken as a pattern by any aspirant to harmacological distinction—his interests were wide and ar-reaching and in later years he did not hesitate to pply his knowledge to subjects important not only to he scientist but also to the practising doctor

His "Mode of Action of Drugs on Cells" constitutes a lea for a wider appreciation of the multitude of variables hich are always operating in experiments on living issues, and Clark rendered a signal service to pharmacological science by his critical analysis of the many "laws" nd hypotheses which had attracted attention, partly on ccount of their misleading simplicity It was a fitting ompliment to his status in the pharmacological world hat he was invited to contribute the volume on general harmacology in Heffter's "Handbuch der Experimentellen Pharmakologie" Here is proof again of his ncyclopædic knowledge of the literature and of his alent for the mathematical interpretation of biological ata although well aware of the limitations to the use of athematics in biology And finally in his "Applied Pharmacology" the author showed a real understanding f the difficulties of the student in a time when there is disastrous tendency to separate the teaching of pharmaology from that of therapeutics The book represents, n his own words, an attempt to 'bridge the gap between pharmacology and therapeutics and to demonstrate as clearly as possible the connection between the two subjects' Its success may be judged from the fact that seven editions have appeared since 1923 and the book has been translated into Chinese and Spanish But his best-seller was undoubtedly a sixpenny monograph in the "Fact" series setting out the scandalous shortcomings of the existing laws on commercial medication which is a model of lucid exposition Clark did not adopt the extreme view that all self-medication is bad, but he showed convincingly how great was the menace of an uncontrolled trade in secret remedies, and with great courage he laid bare the stranglehold which this trade exerts on the lay press His agile brain was quick to discover the ludicrous anomalies in this part of our legal system It is one of the unkind ironies of fate that he should die in the prime of life and just at the time when legislation long overdue has found its way to the statute book

HERBERT RITCHIE SPENCER

M D LOND, LL D ABERD, F R C P

IN the death of Dr Herbert Spencer at the age of 81 there passes from us the last of the great men responsible in this country for the awakening of modern midwifery and gynæcology He was named after his uncle, the Victorian philosopher, from whose influence he derived the catholic outlook combined with accuracy of detail that gave such depth to his opinion At the early age of 31 he became obstetric member of the U C H staff under Sir John Williams, with charge of an outside maternity averaging over 2000 cases yearly this gave him an immense experience in routine midwifery, and the low maternal death-rate was evidence of his skill as a master-craftsman When Williams retired Spencer as senior gynæcologist was able to develop the proper place of cæsarean section in difficult labour He was one of the first to introduce saline transfusion for grave hæmorrhage to recognise the importance of antenatal treatment, and to diagnose the correct presentation of the infant before labour Throughout his 38 years of hospital practice Spencer bore the stigma of professional aristocracy which led a colleague in his valedictory to say "So we see in Spencer an unusual personality, and when he leaves us we shall do more than miss his presence in the ward we shall look back, we who remember his work, and say We are glad to have been students in the Spencer era" And others may apply to himself the closing words of his Harveian oration " that most worthy, good and learned Dr, whose memory ought to bee had for ever in great esteem with midwives and child-bearing women"

Herbert Ritchie Spencer came of an old Warwickshire family, his father was associated with Thomas Brassey as a railroad contractor, and before entering University College, London, in 1879 he had had a strict grammar school education at Atherstone which left him with the love of the classics and the aptitude for modern languages that appears in his writings After qualifying in 1883 he held house appointments at U C H after which Gowers opened the way to an Australasian tour with the Earl of Bantry, and Wilson Fox one to Europe with the Earl of Dalhousie To Gowers he also owed the introduction to shorthand which made his case-notes so compendious and attractive with their cunning coloured drawings Pity that these are destined to remain hidden in hospital records His first published work to attract attention was a laborious study of the visceral hæmorrhages in the stillborn based on a series of 180 autopsies This enabled him to poke inimitable but devastating fun many years later at the "astonished" children born by Delmas's method of *accouchement sur rendezvous* All his later writings were of the same character for Spencer held it was better to place on record full and careful observations from which

ZINC CHLORIDE FOR FIRE FIGHTING

SIR,—I am at a loss to understand the objection taken by Messrs Parker, Moir & Co to my letter of May 24. This letter dealt solely with the dangers from a medical point of view which might arise from the use of solutions of zinc chloride, and I was careful to say that I was not in a position to express any opinion as to whether such solutions were greatly superior to water, but that unless that was so the possible dangers were such that the public should not be allowed unrestricted use of them. I would again emphasise that I have no knowledge of fire-fighting methods. Messrs Parker, Moir & Co state that Incendex (which contains zinc chloride) is over 70 times as efficient as water; therefore to use my expression such a solution is greatly superior to water and thus fulfils the conditions for use by the public.

In their letter of Aug. 30 they urge that a method must be devised to beat more efficiently the incendiary bomb and it is clear that they fully realise the nation-wide importance of this. Therefore I feel sure that they would not assert that their preparation was 70 times as efficient as water unless they were capable of satisfying the most stringent tests and had succeeded in convincing those who are responsible for our fire-fighting services. At the same time I feel it my duty to mention leaflet No. 4 published by the Fire Prevention Executive in which is quoted the following statement made by the Joint Parliamentary Secretary to the Ministry of Home Security in the House of Commons on May 21:

> "A number of proprietary chemical liquids are being sold, some at high prices, for which it is claimed that they readily extinguish incendiary bombs. Many of these have been tested by the Research and Experiments Department of the Ministry of Home Security, but in no case has any been found which can be recommended in preference to water. There is no substantial difference in their favour in the time taken to extinguish a bomb. Apart from this a far more important consideration is the necessity to be in a position to deal immediately with surrounding materials which are often set on fire by the bomb. For the dual purpose of extinguishing the bomb and the fire it causes, there is no liquid as cheap or as readily obtainable as water. Moreover, some of the liquids being sold are corrosive, some contain caustic substances dangerous to the eyes and others produce fumes and smoke which may be harmful, and in any case make fire fighting difficult. In these circumstances expenditure incurred on any such liquids would not be recognised for purposes of grant."

St Mary's Hospital, Paddington. G. ROCHE LYNCH.

"MOTHERS CAN SAVE 50,000 GALLONS OF MILK"

SIR,—Under this heading there appears in the provincial press a report of an address given as part of Sunderland's Food Week where the speaker is alleged to have said that if mothers would breast-feed their infants this large quantity of cow's milk could be saved per year in a town of Sunderland's size. It is time that such erroneous propaganda was stopped. More cannot be got out of anything than is put in. One of the important constituents of milk is calcium and this can only be derived from two sources (*a*) the mother's food and (*b*) the mother's bones. A diet low in calcium inevitably leads to a loss of lime from the maternal skeleton and teeth. To prevent this all too common a disaster, the food must be richer in calcium salts for a nursing mother than for one not suckling her infant. If her intake of cow's milk is not to be markedly increased during this critical period, some other foods rich in lime must be substituted. What are these foods? Apart from cheese, which is a milk product, we have the green vegetables, eggs and nuts. It has clearly been shown by experiments on lactating women that the bulk of green vegetables, &c., that must be fed to supply the necessary amount of calcium is so great as to produce digestive disturbances and subsequent lack of appetite for such foods. This leaves us with milk, milk products and eggs as main sources of food calcium. Dietetic experts are agreed that increased milk intake is the best means of nsuring a good milk output in the human. To this end ot [illegible]nistry of Food arranges that pregnant and lactat- sidere[illegible]ers shall have priority in the distribution of of 0 S g[illegible]. For every pint of milk produced at least a pint of milk must be given to the mother. That is, t would be no saving of cow's milk by a more comm practice of breast-feeding—if the mother's health is to be preserved.

DRUG-FAST BACTERIA

SIR,—In your annotation of Aug. 23 you say that in the treatment of gonorrhœa with sulphanilamide a proportion of cases fail to react to the drug, and that most of these refractory cases, usually as a result of early insufficient dosage, have responded to treatment with the more active sulphapyridine. I agree that drug resistance is usually due to insufficient early dosage but there are some cases where the dosage has been adequate. Judging from one's failures alone there is very little to choose between the results obtained with sulphanilamide and sulphapyridine. Until the introduction of sulphathiazole changing from one sulphonamide to another, including sulphapyridine, had no effect on these resistant infections and the gonococcal discharge persisted. Sulphathiazole, which is even more rapid in its action than sulphapyridine, does cure some of these drug fast cases, but fever therapy is still necessary in the treatment of the failures.

Wimpole Street, W.1. A. H. HARKNESS.

A FATHER OF PUBLIC HEALTH

Johann Peter Frank, the pioneer of public health in Germany, has been strangely neglected, even in his own country; a few partial studies on single aspects have appeared from time to time, but no comprehensive treatise. One of the few German publications lately reaching England is a book by Dr. Hellmut Haubold on the life and work of Frank[1], but the reader is likely to find his expectation changing to foreboding when he sees the foreword by Gauleiter Burckel. Both expectation and foreboding are partly realised. Frank's biography occupies rather less than half the volume—hardly sufficient space in which to do justice to the subject. Several chapters in his life—notably his 10 years work in Italy, for which abundant material is available—are disposed of very summarily in order to leave space for a fuller treatment of the Viennese period. Then follow nine short chapters on various aspects of his work, with special emphasis on its philosophical aspects; it is here that National-Socialist prejudices, which obtrude occasionally throughout the book, are most in evidence. About a third of the whole is taken up with extracts from Frank's great "System einer vollstandigen medizinischen Polizey," selected almost exclusively to illustrate his views as a *Rassenpolitiker*. Frank's Medical Polity is a classical work of 18th century absolutism: the ruler of a state is regarded as standing to his subjects in the relation of a father to his children, amongst his duties being the preservation of the people's health and the promotion of a healthy race by appropriate laws. Frank's idea of the state was naturally that of the political structure he saw around him in the Empire of the period, with its conglomeration of German, Magyar, Slavonic and Baltic peoples. He lacked the concept of his contemporary Herder, of the nation as a mythical biological (racial) and political unity. According to Haubold, it is the tragedy of Germany that she had had to wait for more than a century before the complementary ideas of Herder and Frank could be united to realise the National-Socialist state of today. The book is thus not the impartial and definitive work on Frank that it might have been; nevertheless, it is the most considerable study which has yet appeared. The chapters on Frank's relations to the philosophical ideas of his time, though somewhat biased, represent an original contribution to our knowledge of this great pioneer in public health.

PADDINGTON MEDICAL SOCIETY.—A clinical meeting of this society will be held at Paddington Hospital, Harrow Road, London, W.9, on Tuesday, Sept. 9, at 2.30 P.M.

Notes, Comments and Abstracts

THE LESSON OF THE ONION

With the collapse of France last year and the difficulty of transport from the Mediterranean the possibility of import of onions ceased. Of this the British became painfully aware last autumn. Our home-grown stock was in no way equal to the demand and prices began to soar to astonishing heights so that the Ministry of Food stepped in and fixed the price. As a result onions practically disappeared from the market. Nor was this the only result. Leeks shot up to as much as a shilling a head in the open market, so keen is the public on the flavour of the onion tribe. Neither the Board of Agriculture nor the Ministry of Food—nor be it said the gardener and allotment holder—were to be caught that way again, and throughout the country could be seen fields and gardens green with the tiny spires of onion seedlings in the spring on land that had never grown onions before. Thinnings of onions were sold as spring onions and so ravenous were the public that microscopic plants sold at 1*d* each. Nor did things stop there. As the onions swelled and no longer by any stretch of imagination could be called spring onions they still found a ready sale at a price (calculated from purchases) of 5*s* 6*d* a pound. The possibility of an autumn crop of onions was being endangered by the cupidity of the grower and the extravagance of the purchaser. The Ministry of Food had to step in again and fix the price of the adolescent onion. Even this has not worked, for it appeared that 7½*d* a pound for salad onions in the hand was better than 5*d* a pound for mature onions in the autumn bush. The Ministry of Food had again to step in and distinguish a spring onion from any other. From the dietetic point of view perhaps the move to check the use of immature onions was questionable though maybe wise from the purely economic point of view. Vegetables are prized (dietetically that is) for their calcium, their iron, their vitamins A and C, and on those scores the spring onion defeats the mature bulb hands down. The respective values per 100 g. (3½ oz.) are for the spring onion 135 mg. Ca, 1.24 mg. Fe, 6000 I.U. vitamin A and 280 I.U. vitamin C, the corresponding figures for the mature onion being 31.2, 0.3, 14 and 52. It is a dietetic problem whether those immature onions should not have been canned against the winter when our sources of calcium, iron and vitamins A and C are diminished rather than allowed to mature, just as it is whether fruits should not be canned rather than jammed.

The onion illustrates the all too familiar observation: leave prices uncontrolled and they soar; control prices and commodities disappear off the market. It happened in the war of 1914–18. *Punch* in a cartoon commented on the fact, a rabbit put into the conjurer's top hat labelled "controlled price" disappeared. The phenomenon has been closely studied both during the interval of uneasy peace and now again by the I.L.O. in the earlier days of this war, and the dilemmas of governments, producers, middlemen and consumers set out for all to read. They do not make for serenity of mind. The function of the Food Controller is "so to guide the trade in the fundamental food commodities as to eliminate vicious speculation, extortion and wasteful practices and to stabilise prices in the essential staples." This has hardly been effected in the onion though whether it is a staple or not is debatable. The public say "yes" and the dietitian gives an ambiguous answer. We have been warned that the danger of piecemeal legislation is that unforeseen results happen. Control the price of X and the price of Y, its near substitute, soars. The onion was controlled and the leek became food for millionaires. "The gradual and inevitable growth of controls over the whole range of food prices due to the unforeseen effects of the control of some of them is a marked characteristic of war-time experience."[1]

How are the price controls to be made? Can they be regulated at some "fair" level (say) cost before the war plus a percentage, or on the basis of present-day costs of production? In the last war Beveridge said they proceeded by way of costings, conference and compromise, and Clynes freely rendered the same idea thus: "price fixing must rest less upon elaborate efforts at ascertaining accurate costs than upon experience and general observations." Price fixing, then, cannot be scientific or accurate and there will always be someone apart from the producer and distributor who feels himself aggrieved by a fixed price. Moreover price fixing without rationing is bound to lead to chicanery. On the other hand if price fixing and rationing are to go hand in hand and never to be separated it would entail a complication in ration books and book-keeping in the shops before which imagination quails. There is thus a dilemma before the Government: either it fails miserably to prevent profiteering or the disappearance of valuable commodities on the one hand, or it holds up the distribution of those commodities by an impossible weight of bureaucracy and book-keeping. It is a dilemma between laissez-faire economics and complete totalitarian economics.

One escape from the dilemma has the support of both economist and dietitian. Maynard Keynes[2] put forward the idea of the free guaranteed issue of an "iron ration" and a similar suggestion was adopted by Orr and Lubbock.[3] This plan appears attractive when dealing with stark necessities, but has failed to impress the bureaucratic mind. It would cut down the huge expenditure on clerical work and would leave the prices of the unnecessary food condiments to find their own economic level. That such ideas have crossed the mind of the Minister of Food has been obvious in sundry outbursts—e.g., the price control of turkeys at Christmas, 1940. The economics of the onion throw some light on the problem. Meantime we must each be content with our seasonal 2 lb.

A COMPACT TRANSFUSION OUTFIT

Drug Houses of Australia Export Ltd., of London, have now available their Soluvac Transfusion Pannier. This contains 4 litres of 5% dextrose in normal saline and a similar quantity in Ringer's solution, 2 litres of normal saline, five sets for giving these solutions complete with filters, two sets for collecting blood from donors, two sets of instruments and accessories, two sets for blood-grouping and twenty ampoules of 100 c.cm. citrate-glucose solution. The necessary parts are packed sterile for use. Solutions for replenishment of panniers are available in cartons of ten flasks.

A NEW BRANCH OF NURSING

Industry needs for the proper care of its members certain social services which may at first sight appear to overlap those already in existence. One of these is nursing. The uses of the nurse are increasingly important in factory life and are by no means confined to the care of the injured but cover a wide field which is preventive as well as curative, educational as well as administrative. A man who has been injured at work differs in no wise as regards the burden to himself and to the community from one who has been sick or injured off duty. Both are temporarily non-producers. In either case if by skilled rehabilitation speedier return to full activity can be procured or if by a system of graded work function and health can be more efficiently restored everyone stands to gain. The practitioner should be able to rely on an intelligent nurse to assist in aftercare and supervise the patient's first efforts to resume modified or full duty; the nurse must of course be well selected and properly trained, and she should have certain temperamental qualities if she is to use to the full her opportunities for the education of juveniles and adolescents in the art of living. Industrial and social legislation is putting more and more on her shoulders. Hers is a very full-time job which demands a set of mental and technical equipment the nature of which it is not easy for her to find clearly defined. Even our own profession is a little hazy about what it is reasonable and proper to expect from the nurse in any plant where as a result of Ministry of Labour initiative or employers' foresight, she has become installed. Miss West has made a valiant attempt to remedy this with her handbook.[4] She knows her job and writes well though some of the deductions could be drawn or on which working theories could be based than to write text-books of ephemeral value His Harveian oration, for instance, by its sheer weight of accumulated evidence established William Harvey as a famous obstetrician although his "medicinal observations" have been lost And the FitzPatrick lectures not only told an entertaining tale of British midwifery but redeemed it from disparaging comparison with the story of progress in other countries In the same way the material content of a Lloyd Roberts lecture and of a presidential address to the Medical Society justified his use of the word renaissance to describe the more recent changes in obstetric practice

Of the personal qualities behind this achievement a colleague writes Herbert Spencer was a striking personality, robust both in body and mind He was a first-class clinician and his knowledge was founded not only on his own large experience but upon a profound acquaintance with the literature of his subject His was indeed one of the most familiar figures in the library of the Royal Society of Medicine An innate dislike for unproven novelties and a marked conservatism made him slow to accept new views or new methods until he had examined them with thoroughness or put them to a practical test It is true that he often clung to old methods when they had been abandoned by others too apt in his opinion to be led away by the glamour of the new, yet his results were so uniformly good that those who had the opportunity of watching his work knew what a master of his craft he really was As a consultant he was reliable and helpful, and although some of his patients were at first a little alarmed by his brusque manner they had implicit faith in his judgment and often came to regard him with affection As a committeeman there were times when his partiality for the rôle of the opposition made him a little trying, but his devotion to his hospital and school, his perfect good-humour and his disinterestedness led his colleagues to forgive and forget the veneer of wayward obstruction As an operator he was methodical and careful, as a teacher sound and accurate, as a clinician painstaking and skilful—a worthy successor to his master John Williams

In his spare time Spencer proved himself no mean sportsman Having carried a gun from a time when it was longer than himself he was a keen and clean shot, he was also a good fisherman and enjoyed all outdoor things, so that his companionship on a country walk was a pleasure His many honours, both abroad and at home, must be left to his memory but his unique library of ancient books on obstetrics dating back to the sixteenth century should be secured by some learned society

DAVID HUGH MANSON-BAHR

M B CAMB, M R C S, D T M & H

David Manson-Bahr, who has died suddenly in Kenya at the age of 25, was the second son of Sir Philip Manson-Bahr and grandson of Patrick Manson Educated at Rugby and Trinity College, Cambridge, he completed his medical education at the London Hospital and qualified in 1940 After serving as house-surgeon at the Northampton General Hospital he entered the Colonial Medical Service and took the diploma in tropical medicine With his heredity and upbringing it was natural that he should be attracted by the many-sided problems of medicine in the tropics and it is sad that he has been cut off at the commencement of a promising career in Kenya Of fine physique he was proficient at all games, especially as a hardworking useful rugby forward He was tried out on several occasions for Cambridge University and played regularly for his hospital and the United Hospitals side He was a prominent member of the Falconers Club, and he was seen at his best flying his falcons, or tramping the fields with his dog and gun He will be greatly missed for his cheerful and generous disposition by a wide circle of friends

JOHN JAMESON EVANS

M B EDIN, M D BIRM, F R C S

Mr Jameson Evans, who died at Aberdovey on Aug 13 in his 70th year was consulting surgeon to the Birmingham Eye Hospital and one of the best-known ophthalmologists in the Midlands He had a profound knowledge of the retina in health and disease and made numerous and valuable contributions to ophthalmic literature, but for the war he would have opened the discussion, at the postponed Oxford Ophthalmological Congress of 1940, on the prevention of operative complications following extraction of cataract As a lecturer he was a master of concise and pregnant exposition and his wide range of culture, his quickness of mind and his abundant human vitality and wit made him a teacher of unusual power Born at Carmarthen he was educated at Lampeter and Edinburgh where he qualified in 1892 with a wide range of honours After three years of surgical residence at the infirmary in his native town he secured a similar appointment at the Birmingham Eye Hospital with which he was associated for the rest of his life In all his work he united a wide and simple human sympathy with a helpfulness that made an abiding impression on those with whom he came in contact He leaves a widow, the daughter of Principal T C Edwards of Aberystwyth, and two sons both of whom are practising medicine He was never happier than at his home and on the links at Aberdovey

ANTHONY JAMES MOON

M B CAMB, LIEUTENANT, R A M C

THE death on active service is announced of Lieutenant Anthony Moon, son of Dr A T Moon of Wallington Lieutenant Moon who was 29 years of age was educated at Tonbridge School, Pembroke College, Cambridge, and the London Hospital, qualifying in 1936 After holding several posts in the outpatient department he was resident in the children's department and the septic block In between his appointments at the London he also spent several months as house-surgeon at the Queen's Hospital, Hackney

French & Co Wallington

"Tony Moon was especially fond of children and he often told me," writes E C B B, "that his ambition was to specialise in that work, as his six months in the children's department were the happiest of his time at the London When he was in charge of the septic wards he showed the greatest keenness in his work, and was at his best in cases of acute osteomyelitis, for its treatment combined his love of children with his interest in the modern therapy of surgical infections At the outbreak of war he was stationed under the E M S at Whipps Cross hospital and his ambition was to form a unit studying the problems of war-wound infection In the country he was never happier than when off on some trip into the wilds either walking, fishing or duck-shooting Tony was a great worker and a grand companion"

In December, 1939, Moon married Aileen Stafford and in March, 1940, he joined the R A M C He was soon transferred to France and died while being evacuated from that country He was last seen attending to the wounded on the deck of his ship five minutes before she turned over and sank

---

MASS RADIOGRAPHY OF POLES IN GERMANY —In a circular issued on April 4 the German minister for the interior made it compulsory to examine by screen or miniature film the chests of all Polish civilian workers on their arrival in Germany The examination will be carried out with the cooperation of the labour exchanges and the workers' cards will be stamped with the date of the examination, but no indication of its result will be shown

Medical News

Society of Apothecaries of London

The following candidates having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery and midwifery —

K J Adams, Univ Coll , H P Anderson, Charing Cross and West Lond , B Berman, St Bart's , E D C Davies, St George's , S Fink Manc , A Hannan, Glasg and West Lond , J H C Hill, St Mary's , and D W Mayman, Guy's and Leeds

Royal Institution

Prof J C Drummond, D Sc , scientific adviser to the Ministry of Food, has been elected Fullerian professor of physiology in the institution in succession to Sir Frederick Keeble, F R S

Tuberculosis Association

A meeting of this society will be held at 26, Portland Place, London, W 1, on Saturday, Sept 13 At 10 30 A M , Dr H V Morlock and Mr P R Allison will read a paper on bronchial obstruction as a factor in pulmonary tuberculosis, and at 2 30 P M Dr P L T Bennett will open a discussion on tuberculosis and the examination of recruits

Hospitals Day for London

This year's second Hospitals Day is to be held on Tuesday, Oct 7, and the London Hospitals Street Collections central committee hope to improve on the record made in May when over £10,000 was collected Suggestions and offers of service will be welcomed by Lord Luke at 36, Kingsway, London, W C 2

The Watch on the Thames

Colonel Mackenzie's consultative committee, under Lord Horder's chairmanship, is to consist of Dr James Ferguson, Dr Mervyn Gordon, F R S , Dr Thomas Orr, Lieut Colonel G S Parkinson and Dr Maitland Radford

Hospitals Year-book 1941

The eleventh issue of this year book opens with a well deserved tribute to the late Mr R H P Orde who designed and edited the book from the start and was a chief factor in getting the Sankey Commission to work Pending the appointment of a successor the year book has been seen through the press by Colonel Woolrych Perowne with the help of Mr A E Ceadel In the usual series of signed essays at the beginning Lord Plender marvels at the steadiness of the voluntary assistance being given to voluntary hospitals, while he notes the tendency for expenditure to increase at a greater rate than receipts , and Sir Bernard Docker insists that voluntary hospitals have every right to payment from the State and the municipalities for services rendered Of poignant but ephemeral interest are two illustrated accounts of bombed hospitals Sir Alfred Webb Johnson records the remarkable achievement of the Joint Red Cross war organisation in converting country houses into auxiliary hospitals, and so providing 10,000 additional beds for civilian sick and convalescent Service patients The usual statistical tables and directory follow On pp 29–30 is a salutary black list of non cooperators, and an excellent general index removes some of the drawbacks of an outsize format

---

The Director of Recruitment, Colonial Medical Service, should now be addressed at 2, Park Street, London, W 1

Appointments

EALES WALLACE, L R C P E , examining factory surgeon for Knowbury, Salop

MACMAHON, P J , L R C P I examining factory surgeon for Stillington, co Durham

Infectious Disease in England and Wales

WEEK ENDED AUGUST 23

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 811 , whooping-cough, 3144 , diphtheria, 746 , paratyphoid, 195 , typhoid, 49 ; measles (excluding rubella), 1454 , pneumonia (primary or influenzal), 372 puerperal pyrexia, 118 , cerebrospinal fever, 112 , poliomyelitis, 24 , polio-encephalitis, 0 , encephalitis lethargica, 2 , dysentery, 170 , ophthalmia neonatorum, 92 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospital of the London County Council on Aug 20 was 1255 , including scarlet fever, 111 , diphtheria, 225 , measles, 62 whooping cough 577 , enteritis 18 , chicken-pox, 39 , erysipelas, 37 , mumps , 6 , poliomyelitis, 1 , dysentery, 7 , cerebrospinal fever, 17 , puerperal sepsis, 15 , enteric fevers, 13 , german measles, 3 , polio encephalitis, 2 , encephalitis lethargica, 1 , other diseases (non infectious) 51 , not yet diagnosed, 70

Deaths —In 126 great towns there were no deaths from scarlet fever or measles, 3 (0) from enteric fever, 19 (3) from whooping-cough, 22 (2) from diphtheria, 32 (5) from diarrhœa and enteritis under 2 years, and 4 (0) from influenza The figures in parentheses are those for London itself

Leyton, Manchester and Cardiff each reported 1 fatal case of enteric fever There were 5 deaths from diarrhœa and 3 from whooping cough at Birmingham

The number of stillbirths notified during the week was 198 (corresponding to a rate of 35 per thousand total births), including 25 in London

Births, Marriages and Deaths

BIRTHS

BODINGTON —On Aug 24, at Winchester, the wife of Lieutenant Jocelyn Bodington, R A M C —a son

(*Wellcome Physiological Research Laboratories*)

IT has been known since the work of Roux and Yersin (1889) that bacterial toxins are precipitated by the addition of potash alum In 1926 Glenny, Pope, Waddington and Wallace showed that toxoids were also precipitated by alum and that a suspension of the precipitate had much higher antigenic efficiency for the same combining power This was demonstrated with guineapigs, rabbits and horses (Glenny and Waddington 1928 Glenny 1930) In 1931 Glenny and Barr investigated the precipitation of diphtheria toxoid by potash alum and emphasised the necessity for removing, as far as possible, non-specific materials from alum-precipitated toxoid intended for human use Further developments of this work have since been published For example the production of toxoid suitable for conversion into alum-precipitated toxoid has been reported by Pope and Linggood (1939) These workers devised a medium of low nitrogen content, which overcame many of the disadvantages of earlier types of medium, and on which it is possible to secure consistently filtrates having an Lf value of about 50 units per c cm (The higher Lf values have been obtained by careful control of the iron content of the medium) These culture filtrates, after conversion into toxoid by formalin, can be purified considerably by suitable treatment with charcoal Other procedures for increasing the purity of the final product have also been introduced

In view of the great importance which these alum-precipitated toxoids have attained as immunising agents, and of the disturbing comments which have lately appeared (Bousfield 1941), we feel that a detailed account of the methods of preparation used in these laboratories would be of value

PREPARATION OF TOXIN AND TOXOID

The toxin is prepared essentially as described by Pope nd Linggood (1939) but the iron content of the medium adjusted by adding 0 025 mg of iron as ferrous sulphate ssolved in sodium citrate to each litre (1 24 g $FeSO_4$ H_2O and 12 g sodium citrate is dissolved in 500 c cm nd 1 c cm of this solution is added to 20 litres of edium) Culture filtrates containing from 40 to 60 f units per c cm are bulked together, and the amino-itrogen content (Pope and Stevens 1939) determined rom this value, the amount of formalin (40% formalde-yde) to be added is determined according to the followng figures

Amino N (mg /10 c cm)	Adjust pH of toxin with acetic acid to	Formalin %
5– 6	7 4	0 4
6– 8	7 5	0 5
8–10	7 6	0 6

The pH of the culture filtrates is adjusted to the value hown before adding formalin , this is necessary to keep the material at a pH between 7 and 8 during toxoiding nd so prevent the production of slow flocculating toxoid Toxoiding is carried out at 37–38° C for 3–4 weeks until the material passes the test described below

In view of the fact that no antitoxin is introduced nto this preparation, it is essential that the toxoid should contain no residual toxicity whatsoever It is our custom, therefore, when the material appears completely toxoided, as judged by the intracutaneous injection of undilute toxoid into guineapigs to repeat this test for non-toxicity using the skin of rabbits, which are even more susceptible than guineapigs to diphtheria toxin This final test is performed on every bottle of every batch intended for use in the preparation of A P T The completely toxoided material is then blended and purified by means of charcoal treatment

Much work has been done in these laboratories with the object of finding the most suitable brand of charcoal for this purpose The object of the charcoal treatment is to remove as much colour and non-specific nitrogenous material as possible, with minimal loss of specific toxoid Some brands of charcoal are quite useless, and one with a selective action is necessary The results of treatment of a single batch with three different brands of charcoal is shown in table I

TABLE I—EFFECT OF VARYING QUANTITIES OF THREE BRANDS OF CHARCOAL ON THE SAME BATCH OF TOXOID

Grammes of charcoal per 100 c cm of toxoid	Charcoal 1		Charcoal 2		Charcoal 3	
	Yield of specific toxoid	Increase in purity	Yield of specific toxoid	Increase in purity	Yield of specific toxoid	Increase in purity
	%		%		%	
1			91 3	1 42		
1 5			84 8	1 53		
2	100	1 36	76 1	1 62	89 1	1 34
3	93 5	1 46	48	1 26	84 8	1 53
4	92 4	1 54			82 6	1 9
5	80 4	1 5			76 1	2 21

The only brand of charcoal which will give a two-fold purification is charcoal 3, 4% of which yields a product containing 82 6% of the original flocculating units, and 1 9 times as pure 5% increases the purity, with a drop in yield to 76% Neither charcoal 1 which is weak in activity, nor charcoal 2, which is overactive and not sufficiently selective, give satisfactory results when compared with charcoal 3, though both will increase the purity of the toxoid to 1 5 times that of the untreated toxoid The amount of a suitable charcoal necessary to purify toxoids in this way varies from one batch of toxoid to another It is therefore necessary to determine the optimum amount to use for each batch of toxoid intended for the preparation of A P T This is done in the experimental laboratory by making mixtures of toxoid with known amounts of charcoal, allowing to stand for a definite period of time, filtering, and comparing the flocculating value and total nitrogen content of the filtrates with those of the untreated toxoid The amount chosen for use in the bulk preparation is one which shows a good increase in purity (Lf doses/mg N) with a reasonable yield of specific toxoid *

A sample of the charcoal-treated bulk toxoid is then investigated in the experimental laboratory to determine the optimal amount of potash alum to add Six different mixtures are made, containing a fixed volume of toxoid and varying quantities of alum (added in the form of a 10% solution) The mixtures are left to stand overnight , the supernatant liquids are then withdrawn and the precipitates washed with saline The saline washing is repeated twice, and is followed by a washing with a solution containing 0 5% disodium phosphate (see Linggood 1939) This washing dissolves out some of the precipitate, and the effect varies according to the quantity of alum added originally to the toxoid With some precipitates the loss of specific toxoid is considerable, but with others it is negligible although much non-specific nitrogenous material may be dissolved out This can be seen in table II After the phosphate washings, the precipitates are given a further washing with saline, and finally suspended in saline to the original volume Each precipitate is then tested for toxoid content by flocculation, and estimations of total nitrogen are made In order to test the alum precipitates by flocculation it is necessary to dissolve them , it is our practice to add a small quantity of sodium citrate crystals to a portion of the suspension and place the mixture in a bath at 45–50° C

The optimal amount of alum to be added to the main bulk of toxoid is decided from considerations of the yield of flocculating units and the purity (Lf/mg N) of the precipitates legalities might have found a happier shelter in an appendix Her little book is a definite contribution both to the war effort and to the process of social rebuilding that must follow There are omissions and debatable points but she has got the spirit of the thing and the essential data which are not otherwise readily obtainable, neatly packed into a concise and basically accurate survey Her book should appeal to practitioners in contact with industry to employers of labour, and to nurses who are already in industry or who are among that band of energetic ardent and yet practical women who are looking for some contribution to the war effort which will carry over into the process of redesigning and rebuilding our shaken social fabric This is a book to read and debate but not lightly to find fault with

---

* We have found that ' Eponit C " charcoal is the most suitable for purifying toxoids, but owing to the war it is no longer obtainable We are now experimenting with various British charcoals and find that these tend to be somewhat overactive but can be used with success in smaller quantities

Medical News

Society of Apothecaries of London

The following candidates having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery and midwifery —

K J Adams, Univ Coll , H P Anderson Charing Cross and West Lond , B Berman St Bart's , E D C Davies, St George's , S Fink Manc , A Hannun, Glasg and West Lond , J H C *Hill, St Mary's , and D W Mayman, Guy's and Leeds*

Royal Institution

Prof J C Drummond, D Sc , scientific adviser to the Ministry of Food, has been elected Fullerian professor of physiology in the institution in succession to Sir Frederick Keeble, F R S

Tuberculosis Association

A meeting of this society will be held at 26, Portland Place, London, W 1, on Saturday, Sept 13 At 10 30 A M , Dr H V Morlock and Mr P R Allison will read a paper on bronchial obstruction as a factor in pulmonary tuberculosis, and at 2 30 P M Dr P L T Bennett will open a discussion on tuberculosis and the examination of recruits

Hospitals Day for London

This year's second Hospitals Day is to be held on Tuesday, Oct 7, and the London Hospitals Street Collections central committee hope to improve on the record made in May when over £10,000 was collected Suggestions and offers of service will be welcomed by Lord Luke at 36, Kingsway, London, W C 2

The Watch on the Thames

Colonel Mackenzie's consultative committee, under Lord Horder's chairmanship, is to consist of Dr James Ferguson, Dr Mervyn Gordon, F R S , Dr Thomas Orr, Lieut Colonel G S Parkinson and Dr Maitland Radford

Hospitals Year-book 1941

The eleventh issue of this year-book opens with a well deserved tribute to the late Mr R H P Orde who designed and edited the book from the start and was a chief factor in getting the Sankey Commission to work Pending the appointment of a successor the year book has been seen through the press by Colonel Woolrych Perowne with the help of Mr A E Ceadel In the usual series of signed essays at the beginning Lord Plender marvels at the steadiness of the voluntary assistance being given to voluntary hospitals, while he notes the tendency for expenditure to increase at a greater rate than receipts, and Sir Bernard Docker insists that voluntary hospitals have every right to payment from the State and the municipalities for services rendered Of poignant but ephemeral interest are two illustrated accounts of bombed hospitals Sir Alfred Webb-Johnson records the remarkable achievement of the Joint Red Cross war organisation in converting country houses into auxiliary hospitals, and so providing 10,000 additional beds for civilian sick and convalescent Service patients The usual statistical tables and directory follow On pp 29–30 is a salutary black list of non cooperators, and an excellent index removes some of the drawbacks of an outsize format

The Director of Recruitment, Colonial Medical Service, should now be addressed at 2, Park Street, London, W 1

Appointments

EALES WALLACE L R C P E , examining factory surgeon for Knowbury, Salop

INCE, J G H , M B Lond , M R C O G consultant obstetrician and gynæcologist for Cornwall

MACMAHON, P J , L R C P I examining factory surgeon for Stillington, co Durham

Infectious Disease in England and Wales

WEEK ENDED AUGUST 23

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 811 , whooping-cough, 3144 , diphtheria, 746, paratyphoid, 195 , typhoid, 49 ; measles (excluding rubella), 1454 , pneumonia (primary or influenzal), 372 puerperal pyrexia, 118 , cerebrospinal fever, 112 poliomyelitis, 24 , polio-encephalitis, 0 ; encephalitis lethargica, 2 , dysentery 170 , ophthalmia neonatorum, 92 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospital of the London County Council on Aug 20 was 1255 , including scarlet fever, 111 , diphtheria, 225 , measles, 62 whooping-cough 577 , enteritis 18 , chicken-pox, 39 , erysipelas, 37 , mumps, 6, poliomyelitis, 1 , dysentery, 7 , cerebrospinal fever, 17 , puerperal sepsis, 15 , enteric fevers, 13 , german measles, 3 , polio encephalitis, 2 , encephalitis lethargica, 1 , other diseases (non infectious), 51 , not yet diagnosed 70

Deaths —In 126 great towns there were no deaths from scarlet fever or measles, 3 (0) from enteric fever, 19 (3) from whooping-cough, 22 (2) from diphtheria, 32 (5) from diarrhœa and enteritis under 2 years, and 4 (0) from influenza The figures in parentheses are those for London itself

Leyton, Manchester and Cardiff each reported 1 fatal case of enteric fever There were 5 deaths from diarrhœa and 3 from whooping cough at Birmingham

The number of stillbirths notified during the week was 198 (corresponding to a rate of 35 per thousand total births), including 25 in London

Births, Marriages and Deaths

BIRTHS

BODINGTON —On Aug 24, at Winchester, the wife of Lieutenant Jocelyn Bodington, R A M C —a son

GIBBS —On Aug 25, at Cobham, the wife of Dr A J Gibbs—a son

OGILVIE —On Aug 28, at Ash, Canterbury, the wife of Dr James Ogilvie—a son

ROSS —On Aug 30, at Farnham, Surrey, the wife of Major K M Ross, R A M C —a son

TISDALL —On Aug 29, at Sutton, the wife of Dr Gerald Tisdall—a daughter

WILLIS —On Aug 27, in London, the wife of Dr Saxby Willis—a daughter

MARRIAGES

HEWLETT—LIVINGSTONE —On Aug 28, in London, Allan Beale Hewlett, M R C S , captain, R A M C , to Louise Livingstone

JAMES—HYMERS —On Aug 2, at Nottingham Nicholas Ernest James, M B , to Catherine Sinclair Hymers of Caithness

STANNING—GILLETT —On Aug 23, at Heyshott, Sussex, John Gordon Stanning paymaster lieutenant, R N to Kathleen Mary Gillett, M R C S

DEATHS

GOODALL —On Sept 2nd at Bournemouth, F C Goodall, Ph C

GRIFFITHS —On Aug 26, at Abercarn Fach, Monmouthshire, Edward Meredith Griffiths, M D Aberd , J P , aged 72

MANSON BAHR —On Aug 27, in Kenya David Hugh Manson Bahr M B Camb , D T M & H aged 25

SPENCER —On Aug 28 in London, Herbert Ritchie Spencer, M D Lond , LL D Aberd , F R C P aged 81

WYNNE ROUW —On Aug 29 at Worthing, Robert Wynne Rouw, M R C S , L D S , consulting dental surgeon to Guy's Hospital

(*Wellcome Physiological Research Laboratories*)

It has been known since the work of Roux and Yersin (1889) that bacterial toxins are precipitated by the addition of potash alum In 1926 Glenny, Pope Waddington and Wallace showed that toxoids were also precipitated by alum and that a suspension of the precipitate had much higher antigenic efficiency for the same combining power This was demonstrated with guineapigs, rabbits and horses (Glenny and Waddington 1928 Glenny 1930) In 1931 Glenny and Barr investigated the precipitation of diphtheria toxoid by potash alum and emphasised the necessity for removing, as far as possible, non-specific materials from alum-precipitated toxoid intended for human use Further developments of this work have since been published For example the production of toxoid suitable for conversion into alum-precipitated toxoid has been reported by Pope and Linggood (1939) These workers devised a medium of low nitrogen content, which overcame many of the disadvantages of earlier types of medium and on which it is possible to secure consistently filtrates having an Lf value of about 50 units per c cm (The higher Lf values have been obtained by careful control of the iron content of the medium) These culture filtrates after conversion into toxoid by formalin, can be purified considerably by suitable treatment with charcoal Other procedures for increasing the purity of the final product have also been introduced

In view of the great importance which these alum-precipitated toxoids have attained as immunising agents and of the disturbing comments which have lately appeared (Bousfield 1941) we feel that a detailed account of the methods of preparation used in these laboratories would be of value

PREPARATION OF TOXIN AND TOXOID

The toxin is prepared essentially as described by Pope and Linggood (1939) but the iron content of the medium is adjusted by adding 0 025 mg of iron as ferrous sulphate dissolved in sodium citrate to each litre (1 24 g $FeSO_4$ $7H_2O$ and 12 g sodium citrate is dissolved in 500 c cm and 1 c cm of this solution is added to 20 litres of medium) Culture filtrates containing from 40 to 60 Lf units per c cm are bulked together, and the amino-nitrogen content (Pope and Stevens 1939) determined From this value, the amount of formalin (40% formaldehyde) to be added is determined according to the following figures

Amino N (mg /10 c cm)	Adjust pH of toxin with acetic acid to	Formalin %
5– 6	7 4	0 4
6– 8	7 5	0 5
8–10	7 6	0 6

The pH of the culture filtrates is adjusted to the value shown before adding formalin , this is necessary to keep the material at a pH between 7 and 8 during toxoiding and so prevent the production of slow flocculating toxoid Toxoiding is carried out at 37–38° C for 3–4 weeks until the material passes the test described below

In view of the fact that no antitoxin is introduced into this preparation, it is essential that the toxoid should contain no residual toxicity whatsoever It is our custom therefore when the material appears completely toxoided, as judged by the intracutaneous injection of undilute toxoid into guineapigs to repeat this test for non-toxicity using the skin of rabbits which are even more susceptible than guineapigs to diphtheria toxin This final test is performed on every bottle of every batch intended for use in the preparation of A P T The completely toxoided material is then blended and purified by means of charcoal treatment

Much work has been done in these laboratories with the object of finding the most suitable brand of charcoal for this purpose The object of the charcoal treatment is to remove as much colour and non-specific nitrogenous material as possible, with minimal loss of specific toxoid Some brands of charcoal are quite useless, and one with a selective action is necessary The results of treatment of a single batch with three different brands of charcoal is shown in table I

TABLE I—EFFECT OF VARYING QUANTITIES OF THREE BRANDS OF CHARCOAL ON THE SAME BATCH OF TOXOID

Grammes of charcoal per 100 c cm of toxoid	Charcoal 1		Charcoal 2		Charcoal 3	
	Yield of specific toxoid	Increase in purity	Yield of specific toxoid	Increase in purity	Yield of specific toxoid	Increase in purity
	%		%		%	
1			91 3	1 42		
1 5			84 8	1 53		
2	100	1 36	76 1	1 62	89 1	1 34
3	93 5	1 46	48	1 26	84 8	1 53
4	92 4	1 54			82 6	1 9
5	80 4	1 5			76 1	2 21

The only brand of charcoal which will give a two-fold purification is charcoal 3, 4% of which yields a product containing 82 6% of the original flocculating units, and 1 9 times as pure 5% increases the purity, with a drop in yield to 76% Neither charcoal 1 which is weak in activity, nor charcoal 2, which is overactive and not sufficiently selective, give satisfactory results when compared with charcoal 3 though both will increase the purity of the toxoid to 1 5 times that of the untreated toxoid The amount of a suitable charcoal necessary to purify toxoids in this way varies from one batch of toxoid to another It is therefore necessary to determine the optimum amount to use for each batch of toxoid intended for the preparation of A P T This is done in the experimental laboratory by making mixtures of toxoid with known amounts of charcoal allowing to stand for a definite period of time, filtering and comparing the flocculating value and total nitrogen content of the filtrates with those of the untreated toxoid The amount chosen for use in the bulk preparation is one which shows a good increase in purity (Lf doses/mg N) with a reasonable yield of specific toxoid *

A sample of the charcoal-treated bulk toxoid is then investigated in the experimental laboratory to determine the optimal amount of potash alum to add. Six different mixtures are made, containing a fixed volume of toxoid and varying quantities of alum (added in the form of a 10% solution) The mixtures are left to stand overnight , the supernatant liquids are then withdrawn and the precipitates washed with saline The saline washing is repeated twice and is followed by a washing with a solution containing 0 5% disodium phosphate (see Linggood 1939) This washing dissolves out some of the precipitate, and the effect varies according to the quantity of alum added originally to the toxoid With some precipitates the loss of specific toxoid is considerable but with others it is negligible although much non-specific nitrogenous material may be dissolved out This can be seen in table II After the phosphate washings, the precipitates are given a further washing with saline and finally suspended in saline to the original volume Each precipitate is then tested for toxoid content by flocculation and estimations of total nitrogen are made In order to test the alum precipitates by flocculation it is necessary to dissolve them , it is our practice to add a small quantity of sodium citrate crystals to a portion of the suspension and place the mixture in a bath at 45–50° C

The optimal amount of alum to be added to the main bulk of toxoid is decided from considerations of the yield of flocculating units and the purity (Lf/mg N) of the precipitates

---

* We have found that ' Eponit C " charcoal is the most suitable for purifying toxoids but owing to the war it is no longer obtainable We are now experimenting with various British charcoals and find that these tend to be somewhat overactive but can be used with success in smaller quantities

This varies not only with the type of medium on which the toxoids are made but from one batch to another made by exactly the same method As in the case of charcoal treatment our aim is to obtain good purification with minimal loss of specific toxoid

TABLE II—EFFECT OF A 0 5% AQUEOUS SOLUTION OF DISODIUM PHOSPHATE ($Na_2HPO_4,12H_2O$) ON WASHED ALUM TOXOID PRECIPITATES

Alum added for precipitation (%)	Control (no disodium phosphate)		Precipitates treated with disodium phosphate	
	Flocculating units in precipitate (%)	Lf doses per mg of N	Flocculating units in precipitate (%)	Lf doses per mg of N
1	94	198	54	295
1 5	97	144	88	265
2	89	125	89	248
3	86	137	86	201
4	83	170	83	270

The bulk toxoid is precipitated aseptically with the amount of alum decided on from these experimental tests, and the same procedure of saline, phosphate, and final saline washings is followed The supernatant liquid is then drawn off and the volume of the suspension made up to about half that of the original toxoid, a sample is then taken This sample is dissolved by means of sodium citrate and tested by flocculation, by calculation from the value so obtained sufficient Merthiolate saline is added to make the A P T contain 50–55 Lf doses per c cm, and a final concentration of 0 01% merthiolate It therefore follows that all our batches are of approximately equal strength as measured by combining-power tests, and as we shall show later there is but little variation in antigenic efficiency as indicated by the antitoxic value of the sera of guineapigs injected with many different preparations

TESTS FOR ANTIGENIC EFFICIENCY

The antigenic efficiency of every batch of A P T is tested in guineapigs, which are injected with two doses either of 0 01 c cm or 0 05 c cm separated by an interval of four weeks Schick tests are done ten or eleven days after the second injection to comply with the regulations under the Therapeutic Substances Act The animals are bled two days later when the tests are read This interval after the injection of the Schick dose of toxin is too short for any immunity response to develop from this injection Determinations of antitoxic value are made on the serum from each guineapig by intradermic titrations in guineapigs or rabbits When sufficient animals are available the serum of each guineapig is tested at approximately 100% differences The final result of each batch of prophylactic is recorded as the geometric mean of the antitoxic values of each guineapig

Use of the geometric mean tends to lay too much stress on the occasional poor responder but is definitely to be preferred to the arithmetical mean or the value of pooled sera During a period of acute shortage of laboratory animals, preliminary tests were made on individual guineapig sera at wide limits, and separate pools were made of those between 0 1 and 1, between 1 and 10, and those over 10 units per c cm The geometric mean of the antitoxic values of the separate pools is taken as the measure of antigenic response We have recorded below only those sera which have been tested individually because the two methods are not strictly comparable When individual tests are done the values recorded are underestimates—e g, a value of 5 is recorded if a serum is known to be over 5 and under 10 units per c cm The method of pooling gives higher figures because the individual value of each pool represents the arithmetic mean of its constituents

Recently we have tested 70 batches of A P T, representing a total of several thousand litres of finished product Of 18 batches tested by means of two injections of 0 01 c cm one failed completely Other tests on the same batch were successful and it is almost certain that some technical error occurred in this test A total of 214 guineapigs were used for testing the other 17 batches Of these, 212 were Schick-negative, of the 2 positive reactors 1 was found to contain under 0 01 unit of antitoxin per c cm and the other over 1 unit, indicating that the Schick test was incorrectly read In experience a non-specific reaction read as positive is v rare, occurring only once in several thousand tests T geometric means of individual values varied from 1 2 to 3 3 with an average of 2 2 units per c cm

A total of 814 guineapigs were used to test 69 batches by means of two injections of 0 05 c cm, all were Schick negative The geometric means of 44 batches individually tested varied from 1 35 to 6 8, averaging 3 9 units per c cm Tests were made at all times of the year using guineapigs from many sources Of all the batches tested only one failed to produce a mean value of at least 2 units per c cm after two injections of 0 05 c cm or less The one failure occurred when rabbits were used for testing the guineapig sera Tests on individual sera show very little scatter (table III)

The majority of guineapigs with 0 005 unit or more of antitoxin per c cm are Schick negative Over 85% of guineapigs injected with two doses of 0 05 c cm contained at least 400 times this amount of antitoxin No quantitative measurement can therefore be made by means of the Schick tests until further work has been done on the effect of much lower doses of A P T The scarcity of experimental animals has prevented our working out the smallest amount of A P T that can be given by the two-dose method which will just produce a Schick negative state in guineapigs, or the dose which will produce this effect when given singly A few tests were made on the response to single injections of 0 05 c cm and all 23 guineapigs injected produced over 0 1 unit in four to six weeks It is possible, however that A P T administered in very small doses involving dilution may be absorbed so rapidly that a true measure of the antigenic efficiency of undilute A P T cannot be gauged by tests made using very small dosage The estimation of the amount of antitoxin produced in guineapigs by a reasonable dosage appears the most satisfactory way of assessing any particular product

TABLE III—TESTS ON INDIVIDUAL SERA

Antitoxic units per c cm	Number of guinea pigs injected with two doses of		Antitoxic units per c cm	Number of guinea pigs injected with two doses of	
	0 01 c cm	0 05 c cm		0 01 c cm	0 05 c cm
Under			1 0	27	33
0 01	1	0	2 0	85	205
0 1	2	5	5 0	43	169
0 2	3	2	10 0	18	61
0 5	12	19	25 0	1	1

An easier method that must be further explored consists of testing the immunity produced in guineapigs by a form of multiple Schick testing The test dose to be used is so large that it need no longer be measured in terms of Schick doses but in terms of the Lf dose of a toxin We have tested three batches of A P T on 44 guineapigs by this method The guineapigs received two injections of 0 05 c cm of A P T at four weeks' interval, twelve days after the last injection they were given 0 1 Lf (100 times Schick dose) and 1 Lf of toxin intracutaneously The smaller dose caused no reaction in any guineapig and 35 (80%) did not react to 1 Lf of toxin We hope shortly to link up the antitoxin produced in guineapigs with their tolerance to toxin in terms of Lf doses and to adopt this method as a routine

DISCUSSION

Our work has been done in the laboratories where the use of alum to enhance the efficiency of antigens was discovered, where alum toxoid was first used in the immunisation of horses, first prepared and recommended for human immunisation, and first given for brevity the name A P T We and former colleagues here have been concerned constantly to improve the product, by aiming at standards of purity and efficiency which have steadily risen with experience The preparation has acquired a wide reputation in the immunisation of children, particularly because of its effectiveness in two doses, in contrast to the usual course of three doses needed with the weaker preparations, T A F, F T and T A M But if a preparation is to be described as A P T, with the implication that it will thus safely immunise in two small doses, it must be prepared and tested by methods which will give it this efficiency, and it seems to us likely that methods which have recently been described by other workers will be found to fall short of this requirement at more than one point

We hope that the procedure we have here described, representing the stage now reached by some ten years of experience, will be further and progressively improved by workers in other laboratories, as well as by ourselves With a view to assisting such progress, it may be useful to set out the following points in our present practice to which we attach importance

1 The aim is to obtain, in the final product, an adequate concentration of flocculation equivalents (we require 50 Lf per c cm) without overloading it with unspecific materials To achieve this we have found it desirable to start with a toxoid having itself about 50 Lf per c cm There may well be methods by which the same specific potency and purity can be attained in an A P.T made from a much weaker toxoid, but we have not yet discovered them

2 Addition of alum is not adjusted to the point of producing the maximum yield of precipitate The amount added is that found, by trial, to give a precipitate of high activity, low content of non specific impurities and a reasonably good yield of the original toxoid

3 We use alum alone for the precipitation A complex containing toxoid can be obtained by adding aluminium hydroxide to formol toxoid, and another by adding alum and acid, but neither of these can be regarded as identical with that produced by alum alone It has been found by some of our colleagues that the precipitate with alum and acid, in particular, contains a more soluble "acid precipitate," in addition to the less soluble "alum precipitate," and it is not safe to assume that these are equal in immunising potency. It was to the alum precipitate alone that the name "A P T" was first applied We plead for its restriction to this original sense Some variation in the immunising potency of preparations giving similar flocculation values may still be inevitable, but it is the more important not to admit any which can be excluded

4 It has long been known that the use of phenol as a preservative, in the final suspension, damages the antigen, so that its immunising potency falls rapidly We avoid using phenol at any stage of the preparation, as well as in the final product

5 The official "test for potency as an immunising antigen," in the regulations under the Therapeutic Substances Act, was formulated in 1931, before A P T came into use, and must obviously have been framed with reference to the types of diphtheria prophylactic then generally available, of which *three* injections are required for immunising a human subject In the absence of any official test specially applicable to A P T, this stronger preparation has only to pass the minimum tests thus prescribed for the earlier and weaker ones It is easy to show that relatively very weak preparations of A P T will pass this guineapig test with ease A P T is a more potent immunising agent, not only of man but of the guineapig, and there is no ground for the assumption that the ratio of its superiority is the same in the two cases Our own evidence suggests that precipitating a toxoid with alum increases its immunising effect, on the guineapig as much as a hundred-fold We have accordingly demanded of our final product, made up to contain 50 Lf per c cm, that, with the two small doses we have indicated, it shall raise the immunity of guineapigs to the level at which they give a negative response, not merely to 1 Schick test dose, but to at least 100 such doses

The advance of knowledge of the properties of A P.T has been so rapid and so recent, and its publication has hitherto been so incomplete and scattered, that official regulations for its control could not be expected to keep pace with the development of its production We hope that the details here recorded will facilitate an early definition of requirements and tests for A P T as such We are familiar with the difficulty of measuring immunising potency with any approach to accuracy, but it is clearly important that official tests shall not be open to wide differences of interpretation It ought to be possible, at least, to ensure and to impose a common aim and understanding with regard to the measurement and notation of the strength of A P T and the consequent adjustment of its dosage

SUMMARY

A P T produced at these laboratories contains 50 Lf doses of toxoid per c cm

Guineapigs receiving two injections of 0 05 c cm (or less) at four weeks' interval produce 2 units of antitoxin per c cm of serum within ten days of the second injection

Such guineapigs can be tested by the intracutaneous injection of from 0 1 to 1 Lf dose of toxin The exact level of immunity to be used as a criterion of potency has not yet been fixed

LIVER EXTRACT IN TREATMENT OF TROPICAL MACROCYTIC ANÆMIA

H C TROWELL, M D Lond, M R C P
MEDICAL OFFICER UGANDA LECTURER IN MEDICINE IN THE UGANDA MEDICAL SCHOOL

THE treatment of nutritional tropical anæmia is not nearly as satisfactory as that of the allied condition, pernicious anæmia Wills (1933) discovered the value of Marmite, and the textbooks still insist on it, but few patients can tolerate the necessary ½–2 oz a day, and the treatment is expensive Wills has now discarded marmite in favour of liver extracts

In pernicious anæmia ½ lb of whole liver daily is usually curative, but in tropical macrocytic anæmia about four times this amount is required, which is too much for any patient to consume Better success has attended the use of crude liver extracts administered by injection

Campolon has been more extensively used than any other product, 1 c cm of the extract is derived from 5 g of raw liver It has given uniformly good results in the hands of more than a dozen different investigators, and cases in which it has proved ineffective have been rare Dosage varies, but most workers find that 5–10 c cm daily is needed, the same dose given once a week is as a rule successful in pernicious anæmia Foy and Kondi (1939) give up to 12 c cm in the hæmolytic variety of macrocytic anæmia, in the non-hæmolytic variety, which seems to be commoner in India than elsewhere, many workers report that campolon is effective when given in doses of only 2 c cm daily This represents experience up to the outbreak of war, when it became increasingly difficult to get campolon I am aware of no reports on Hepatex Some reports, favourable on the whole, have been made on the more potent Neo-hepatex, Wills (1938) used it successfully on 4 cases of non-hæmolytic macrocytic anæmia, Anderson and Roberts (1940) gave 2 c cm daily for three days, and then 2 c cm weekly to 4 adult cases, 2 of which appear to fall into the hæmolytic variety of Fairley (1938) and 2 into the non-hæmolytic variety of Wills In 9 cases of my own, neo-hepatex was successful in 6 and failed in 3, owing either to intercurrent disease (chronic nephritis or tuberculosis) or to insufficient dosage When less than 2 c cm was given daily the response was poor, and in some cases 4 c cm was needed My experience confirms that of others that larger doses are required for the hæmolytic variety of the disease (Trowell 1940) As far as I know, nobody has reported total failure with neo-hepatex Hepatex-T contains liver, vitamin B_1, riboflavine, nicotinic acid and vitamin B_6 I have seen no reports on its effects, and it seems to me unsatisfactory to administer a mixture of liver and the vitamin-B complex

Earlier work on marmite led to the hope that the vitamin-B complex would yield either Castle's extrinsic factor or else some hæmopoietic factor needed in the

This varies not only with the type of medium on which the toxoids are made but from one batch to another made by exactly the same method As in the case of charcoal treatment our aim is to obtain good purification with minimal loss of specific toxoid

TABLE II—EFFECT OF A 0 5% AQUEOUS SOLUTION OF DISODIUM PHOSPHATE ($Na_2HPO_4,12H_2O$) ON WASHED ALUM TOXOID PRECIPITATES

Alum added for precipitation (%)	Control (no disodium phosphate)		Precipitates treated with disodium phosphate	
	Flocculating units in precipitate (%)	Lf doses per mg of N	Flocculating units in precipitate (%)	Lf doses per mg of N
1	94	198	54	295
1 5	97	144	88	265
2	89	125	89	248
3	86	137	86	201
4	83	170	83	270

The bulk toxoid is precipitated aseptically with the amount of alum decided on from these experimental tests, and the same procedure of saline, phosphate, and final saline washings is followed The supernatant liquid is then drawn off and the volume of the suspension made up to about half that of the original toxoid, a sample is then taken This sample is dissolved by means of sodium citrate and tested by flocculation, by calculation from the value so obtained sufficient Merthiolate saline is added to make the A P T contain 50–55 Lf doses per c cm, and a final concentration of 0 01% merthiolate It therefore follows that all our batches are of approximately equal strength as measured by combining-power tests, and as we shall show later there is but little variation in antigenic efficiency as indicated by the antitoxic value of the sera of guineapigs injected with many different preparations

TESTS FOR ANTIGENIC EFFICIENCY

The antigenic efficiency of every batch of A P T is tested in guineapigs, which are injected with two doses either of 0 01 c cm or 0 05 c cm separated by an interval of four weeks Schick tests are done ten or eleven days after the second injection to comply with the regulations under the Therapeutic Substances Act The animals are bled two days later when the tests are read This interval after the injection of the Schick dose of toxin is too short for any immunity response to develop from this injection Determinations of antitoxic value are made on the serum from each guineapig by intradermic titrations in guineapigs or rabbits When sufficient animals are available the serum of each guineapig is tested at approximately 100% differences The final result of each batch of prophylactic is recorded as the geometric mean of the antitoxic values of each guineapig

Use of the geometric mean tends to lay too much stress on the occasional poor responder but is definitely to be preferred to the arithmetical mean or the value of pooled sera During a period of acute shortage of laboratory animals, preliminary tests were made on individual guineapig sera at wide limits, and separate pools were made of those between 0 1 and 1, between 1 and 10, and those over 10 units per c cm The geometric mean of the antitoxic values of the separate pools is taken as the measure of antigenic response We have recorded below only those sera which have been tested individually because the two methods are not strictly comparable When individual tests are done the values recorded are underestimates—*e g*, *a value of 5 is recorded if a serum* is known to be over 5 and under 10 units per c cm The method of pooling gives higher figures because the individual value of each pool represents the arithmetic mean of its constituents

Recently we have tested 70 batches of A P T, representing a total of several thousand litres of finished product Of 18 batches tested by means of two injections of 0 01 c cm one failed completely Other tests on the same batch were successful and it is almost certain that some technical error occurred in this test A total of 214 guineapigs were used for testing the other 17 batches Of these, 212 were Schick-negative of the 2 positive reactors 1 was found to contain under 0 01 unit of antitoxin per c cm and the other over 1 unit, indicating that the Schick test was incorrectly read In experience a non-specific reaction read as positive is v rare, occurring only once in several thousand tests geometric means of individual values varied from 1 2 3 3 with an average of 2 2 units per c cm

A total of 814 guineapigs were used to test 69 batches by means of two injections of 0 05 c cm, all were Schick negative The geometric means of 44 batches individually tested varied from 1 35 to 6 8, averaging 3 9 units per c cm Tests were made at all times of the year using guineapigs from many sources Of all the batches tested only one failed to produce a mean value of at least 2 units per c cm after two injections of 0 05 c cm or less The one failure occurred when rabbits were used for testing the guineapig sera Tests on individual sera show very little scatter (table III)

The majority of guineapigs with 0 005 unit or more of antitoxin per c cm are Schick negative Over 85% of guineapigs injected with two doses of 0 05 c cm contained at least 400 times this amount of antitoxin No quantitative measurement can therefore be made by means of the Schick tests until further work has been done on the effect of much lower doses of A P T The scarcity of experimental animals has prevented our working out the smallest amount of A P T that can be given by th two-dose method which will just produce a Schick negative state in guineapigs, or the dose which will produce this effect when given singly A few tests were made on the response to single injections of 0 05 c cm and all 23 guineapigs injected produced over 0 1 unit in four to six weeks It is possible however that A P T administered in very small doses involving dilution may be absorbed so rapidly that a true measure of the antigenic efficiency of undilute A P T cannot be gauged by tests made using very small dosage The estimation of the amount of antitoxin produced in guineapigs by a reasonable dosage appears the most satisfactory way of assessing any particular product

An easier method that must be further explored consists of testing the immunity produced in guineapigs by a form of multiple Schick testing The test dose to be used is so large that it need no longer be measured in terms of Schick doses but in terms of the Lf dose of a toxin We have tested three batches of A P T on 44 guineapigs by this method The guineapigs received two injections of 0 05 c cm of A P T at four weeks' interval, twelve days after the last injection they were given 0 1 Lf (100 times Schick dose) and 1 Lf of toxin intracutaneously The smaller dose caused no reaction in any guineapig and 35 (80%) did not react to 1 Lf of toxin We hope shortly to link up the antitoxin produced in guineapigs with their tolerance to toxin in terms of Lf doses and to adopt this method as a routine

DISCUSSION

Our work has been done in the laboratories where th use of alum to enhance the efficiency of antigens wa discovered, where alum toxoid was first used in the immunisation of horses, first prepared and recommended for human immunisation, and first given for brevity, the name A P T We and former colleagues here have been concerned constantly to improve the product, by aiming at standards of purity and efficiency which have steadily risen with experience The preparation ha acquired a wide reputation in the immunisation of children, particularly because of its effectiveness in two doses, in contrast to the usual course of three doses needed with the weaker preparations, T A F, F T and T A M But if a preparation is to be described as A P T, with the implication that it will thus safely immunise in two nall doses, it must be prepared and tested by methods hich will give it this efficiency, and it seems to us kely that methods which have recently been described y other workers will be found to fall short of this equirement at more than one point

We hope that the procedure we have here described epresenting the stage now reached by some ten years of xperience will be further and progressively improved by workers in other laboratories as well as by ourselves With a view to assisting such progress it may be useful to set out the following points in our present practice to which we attach importance

1 The aim is to obtain, in the final product an adequate concentration of flocculation equivalents (we require 50 Lf per c.cm.) without overloading it with unspecific materials To achieve this we have found it desirable to start with a toxoid having itself about 50 Lf per c cm There may well be methods by which the same specific potency and purity can be attained in an A.P.T made from a much weaker toxoid but we have not yet discovered them.

2. Addition of alum is not adjusted to the point of producing the maximum yield of precipitate The amount added is that found by trial, to give a precipitate of high activity low content of non-specific impurities and a reasonably good yield of the original toxoid

3 We use alum alone for the precipitation. A complex containing toxoid can be obtained by adding aluminium hydroxide to formol toxoid, and another by adding alum and acid but neither of these can be regarded as identical with that produced by alum alone It has been found by some of our colleagues that the precipitate with alum and acid in particular, contains a more soluble "acid precipitate," in addition to the less soluble "alum precipitate," and it is not safe to assume that these are equal in immunising potency It was to the alum precipitate alone that the name "A.P.T" was first applied We plead for its restriction to this original sense Some variation in the immunising potency of preparations giving similar flocculation values may still be inevitable, but it is the more important not to admit any which can be excluded.

4. It has long been known that the use of phenol as a preservative in the final suspension, damages the antigen, so that its immunising potency falls rapidly. We avoid using phenol at any stage of the preparation, as well as in the final product

5 The official "test for potency as an immunising antigen," n the regulations under the Therapeutic Substances Act, was ormulated in 1931 before A.P T came into use and must bviously have been framed with reference to the types of iphtheria prophylactic then generally available, of which two injections are required for immunising a human subject n the absence of any official test specially applicable to A.P T. this stronger preparation has only to pass the minimum ests thus prescribed for the earlier and weaker ones It is easy to show that relatively very weak preparations of A.P T will pass this guineapig test with ease A.P T. is a more potent immunising agent, not only of man but of the guineapig and there is no ground for the assumption that the ratio of its superiority is the same in the two cases Our own evidence suggests that precipitating a toxoid with alum increases its immunising effect on the guineapig as much as a hundredfold. We have accordingly demanded of our final product, made up to contain 50 Lf per c.cm., that, with the two small doses we have indicated, it shall raise the immunity of guineapigs to the level at which they give a negative response, not merely to 1 Schick test dose, but to at least 100 such doses

The advance of knowledge of the properties of A.P.T has been so rapid and so recent and its publication has hitherto been so incomplete and scattered that official regulations for its control could not be expected to keep pace with the development of its production. We hope that the details here recorded will facilitate an early definition of requirements and tests for A.P T as such We are familiar with the difficulty of measuring immunising potency with any approach to accuracy, but it is clearly important that official tests shall not be open to wide differences of interpretation. It ought to be possible at least to ensure and to impose a common aim and understanding with regard to the measurement and notation of the strength of A.P T and the consequent adjustment of its dosage

SUMMARY

A P T produced at these laboratories contains 50 Lf doses of toxoid per c cm

Guineapigs receiving two injections of 0 05 c.cm (or less) at four weeks' interval produce 2 units of antitoxin per c cm. of serum within ten days of the second injection

Such guineapigs can be tested by the intracutaneous injection of from 0 1 to 1 Lf dose of toxin The exact level of immunity to be used as a criterion of potency has not yet been fixed

LIVER EXTRACT IN TREATMENT OF TROPICAL MACROCYTIC ANÆMIA

H. C. TROWELL. M D. Lond. M R C P

MEDICAL OFFICER, UGANDA; LECTURER IN MEDICINE IN THE UGANDA MEDICAL SCHOOL

THE treatment of nutritional tropical anæmia is not nearly as satisfactory as that of the allied condition, pernicious anæmia Wills (1933) discovered the value of Marmite and the textbooks still insist on it: but few patients can tolerate the necessary 1–2 oz a day; and the treatment is expensive. Wills has now discarded marmite in favour of liver extracts.

In pernicious anæmia ½ lb of whole liver daily is usually curative, but in tropical macrocytic anæmia about four times this amount is required which is too much for any patient to consume Better success has attended the use of crude liver extracts administered by injection.

Campolon has been more extensively used than any other product: 1 c cm. of the extract is derived from 5 g of raw liver. It has given uniformly good results in the hands of more than a dozen different investigators, and cases in which it has proved ineffective have been rare. Dosage varies but most workers find that 5–10 c cm daily is needed: the same dose given once a week is as a rule successful in pernicious anæmia Fox and Kondi (1939) give up to 12 c cm. in the hæmolytic variety of macrocytic anæmia: in the non-hæmolytic variety, which seems to be commoner in India than elsewhere many workers report that campolon is effective when given in doses of only 2 c cm. daily This represents experience up to the outbreak of war, when it became increasingly difficult to get campolon. I am aware of no reports on Hepatex Some reports favourable on the whole, have been made on the more potent Neo-hepatex: Wills (1938) used it successfully on 4 cases of non-hæmolytic macrocytic anæmia: Anderson and Roberts (1940) gave 2 c cm. daily for three days and then 2 c cm. weekly to 4 adult cases 2 of which appear to fall into the hæmolytic variety of Fairley (1938) and 2 into the non-hæmolytic variety of Wills. In 9 cases of my own, neo-hepatex was successful in 6 and failed in 3 owing either to intercurrent disease (chronic nephritis or tuberculosis) or to insufficient dosage. When less than 2 c cm was given daily the response was poor and in some cases 4 c cm was needed. My experience confirms that of others that larger doses are required for the hæmolytic variety of the disease (Trowell 1940) As far as I know, nobody has reported total failure with neo-hepatex. Hepatex-T contains liver, vitamin B_1 riboflavine nicotinic acid and vitamin B_6 I have seen no reports on its effects, and it seems to me unsatisfactory to administer a mixture of liver and the vitamin-B complex

Earlier work on marmite led to the hope that the vitamin-B complex would yield either Castle's extrinsic factor or else some hæmopoietic factor needed in the pernicious-anæmia group Attempts to isolate these factors have failed, and the administration of fractions of the vitamin-B complex in tropical macrocytic anæmia rests on no certain scientific basis

Anahæmin an extremely concentrated liver fraction, though effective in the treatment of pernicious anæmia has been found to have only a limited action in tropical microcytic anæmia Wills (1938) has never found that non-hæmolytic cases in pregnant women respond Napier and his colleagues (1938) found anahæmin curative in 3 out of 6 cases of macrocytic anæmia I have made fair trial of anahæmin in only 3 cases of the hæmolytic variety of the disease, giving from 8 to 14 c cm in single doses and assessing the reticulocyte response and the change in the blood-count, the cases showed little or no response Recently Foy and Kondi (1939) found that anahæmin in very large doses produced a satisfactory response in these cases, and Fairley (1940) has reported 1 non-hæmolytic case in which 64 c cm of anahæmin was given before the blood-count became normal An ordinary case of pernicious anæmia recovers in a few weeks on 1–2 c cm of anahæmin a month, which gives some measure of the size of the dose required in tropical macrocytic anæmia Treatment is thus expensive if anahæmin is used, and Fairley recommends cruder preparations It seems that some fractions essential to the cure of tropical macrocytic anæmia are lost in the refining process I have received some of these fractions from British Drug Houses and it may be possible to test them later on proved cases, but it seemed wise to issue this preliminary note because the only preparation which will be on the market for some time to come will be their liver extract for injection

To test a new preparation it is necessary to find uncomplicated and proved cases of the disease Out of 12 cases of tropical macrocytic anæmia treated in my wards during 1940, 2 were chosen because they showed little or no evidence of intercurrent disease, many of our cases are complicated by malaria, hookworm disease, yaws, syphilis, tuberculosis or nephritis

CASE-REPORTS

Case 1 —A man aged 25, admitted on May 27, 1940, had had malaise for an indefinite time and abdominal swelling for 2 weeks Nutrition fair, temperature normal, pallor, no œdema, slight jaundice Border of spleen palpable at umbilicus, firm but not tender Liver not palpable No other physical signs A blood film showed no parasites Kahn test negative Stools no ova seen, tænia segments passed occasionally, occult blood test negative Test meal, normal free hydrochloric acid Urine a trace of albumin Van den Bergh reaction indirect positive 2 4 mg Blood-count on May 29 showed red cells, 1,500,000, 3 megaloblasts of Ehrlich to every 100 white cells, reticulocytes 8 5%, Hb (Sahli) 34%, colour index (corrected) 1 35; mean cell diameter, 7 6 μ, mean cell volume, 133 3 cu μ, white cells, 6200 (polymorphs 43%, lymphocytes 45%, eosinophils 12%) Examination of bone marrow on June 1 showed white cells 62%, red cells 38% (late erythroblasts 7%, basophilic normoblasts 9%, polychromasic normoblasts 11%, orthochromic normoblasts 7%, megaloblasts of Ehrlich 4%), smear rather acellular Splenic smear on the same day showed reticulo endothelial cells 78%, neutrophils 9%, lymphocytes 9%, eosinophils 1%, late erythroblasts 1%, megaloblasts of Ehrlich 2%, hæmosiderin pigment was present

June 3, injection of liver extract (B D H) 5 c cm given June 6, reticulocyte crisis to 13 2% June 10, 5 c cm of extract injected, June 20, 18 c cm Steady rise of weekly red cell count, at first slowly then more rapidly to 4,120,000, with Hb 60%, on July 4 Spleen decreased slightly in size and was four finger breadths below the costal margin on July 8 when he was discharged

Case 2 —A woman aged 30, admitted on May 11, 1940, had felt well until she developed bronchitis about a week before admission Nutrition good, pallor, moderate jaundice, border of spleen at umbilicus, very tender Temperature 100° F, pulse rate 140 Mild bronchitis and basal congestion No other physical signs Blood film, no parasites Kahn test negative Stools contained a few hookworm ova Occult-blood test weakly positive Urine normal Van den Bergh, 2 mg, indirect positive Test meal, hydrochloric acid normal Blood-count on May showed red cells 1,760,000, Hb 32%, C I 1 09 May bronchitis settling, blood count red cells 1,800,000 nucleated reds, including 1 megaloblast of Ehrlich, to every 100 white cells, reticulocytes 3 2%), Hb 35%, C I 1 16, M C V 100 cu μ, white cells 3800 (polymorphs 47%, lymphocytes 36%, monocytes 9%, eosinophils 8%) Sternal marrow hæmocytoblasts 2%, early erythroblasts 11%, late erythroblasts 32%, basophil normoblasts 1%, no myelocytes, metamyelocytes 6%, stab cells 8%, neutrophils 3%, proportion of red cells to white cells, 6 1, marrow very cellular, showing active erythropoiesis of normal type, with no tendency towards the megaloblastic change of pernicious anæmia Three subtertian schizonts seen in 100 fields, indicating chronic malaria in the latent stage, no parasites found in circulating blood, though doubtless a few would appear from time to time The blood picture showed no change after quinine, gr 30, had been taken for a week, and I believe malaria played no part in the anæmia

On May 23, *neo hepatex injections were begun, 4 c cm* being given daily until May 30 On May 28 there was a reticulocyte crisis of 12%, and the hæmoglobin rose rapidly to 46% On May 30 the red cells had risen to 2,840,000 Soon after the injections were stopped the blood picture became stationary and remained so from June 3 to 6, when *the red cells were 3,400,000, Hb 50% On June 7 liver* extract (B D H) 5 c cm was given and the hæmoglobin rose at once to 65% and the red cells to *4,420,000*, no reticulocyte crisis was detected, but there was a slight rise of reticulocytes from 5 4% on June 1 *to 7% on the 14th* The spleen was four finger-breadths below the costal margin when the patient was discharged on June 15

SUMMARY

Two cases of tropical macrocytic anæmia, uncomplicated by serious intercurrent disease, showed satisfactory response to liver extract (B D H) given in doses of 5–10 c cm weekly The extract may prove to be more effective in the treatment of this type of anæmia, as well as cheaper, than the refined liver extracts which are potent in the treatment of pernicious anæmia

I wish to thank the Hon D M S Uganda for permission to publish this article

SIMPLE SYSTEM OF SPLINTING FOR LOWER LIMB

I S Smillie,
M B EDIN, F R C S E, F R F P S
ORTHOPÆDIC SURGEON, SCOTTISH E M S

In the last quarter of 1939 our attention was focused on the provision of accommodation and equipment for the treatment of increased numbers of fractures, both simple and compound For injuries of the lower limb it seemed certain that splints of the last war—the Thomas and Braun—and the more recent Bohler modification of the Braun splint would find almost universal favour Further consideration of the Braun splint for the tibia, and Bohler-Braun modification for femur, showed that certain disadvantages which these splints possess become accentuated by the conditions of modern war Being somewhat awkward and bulky they are difficult to store and not easily transportable They require some form of fixation to the foot of the bed, and for ease of nursing and the patient's comfort require to be constructed for both right and left sides An important disadvantage is the quantity of metal they contain

About four years ago a simple wooden bed-rest was constructed for use in conjunction with the Thomas plint and is now used in many hospitals It has been llustrated elsewhere[1] but not previously described he simple method of splinting for the lower limb bout to be described is based on this est It is proposed to describe its onstruction and mode of use in onjunction with a Thomas splint or simple fractures of the femur, and to explain the few additions which convert it into either a Braun or a Böhler-Braun splint

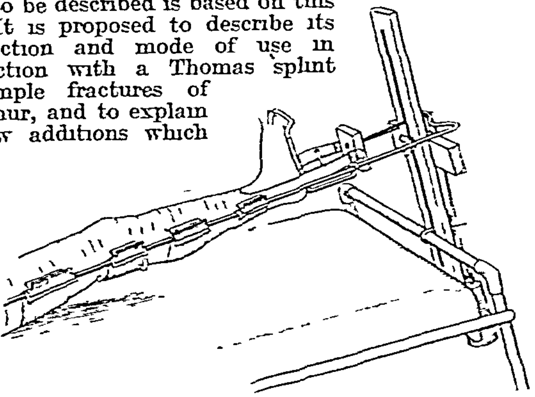

FIG 1—Wooden rest used for supporting and fixing Thomas splint to foot of bed.

The Thomas splint rest consists of two strips of wood 3 ft 9 in × 3 in × $\frac{3}{4}$ in and 12 in × 3 in × $\frac{3}{4}$ in In the larger a $\frac{1}{2}$ in slot is cut which runs almost from end to end, small sections of wood being retained intact at one extremity and in the centre to maintain the strength of the strip On the smaller, which is drilled centrally to carry a $\frac{5}{16}$ in bolt, are mounted two pulleys to carry the extension cord Two hooks, threaded $\frac{5}{16}$ in and fitted with wing nuts and washers of large surface area, pass through the slot and attach the upright portion to the bars at the foot of the bed, while the shorter horizontal portion is attached and adjusted for height by a straight $\frac{5}{16}$ in bolt and wing nut (figs 1 and 2)

Method of use with a Thomas splint—It will be seen from fig 1 that this rest has the advantage of maintaining permanent fixation of the distal extremity of a Thomas splint in the horizontal position at the desired height This fixation allows the lower end of the bed to be raised, which causes the patient s body-weight to exert counter extension, thus increasing the distraction at the site of the fracture while preventing undesirable pressure by the ring of the splint on the ischial tuberosity When the Thomas splint is too long in relation to the patient's height and the length of the bed, a point of fixation nearer the proximal end is obtained by inserting an adjustable "hand rest" between the horizontal metal rods of the splint All additional apparatus should be oided, but in certain cases where nursing is difficult may be necessary to provide weight suspension of the ring of the splint from a Balkan beam There is no known method of either "fixed" or "weight" extension which does not require constant care and attention if the optimum results are to be obtained However, it is claimed for this simple splint rest that the necessity for constant adjustments is reduced to a minimum

Conversion to Braun or Böhler-Braun type of splint—It will be seen from figs 2 and 3 that the Thomas splint rest is converted into a Braun type splint by the addition of two bent strips of $\frac{3}{4}$ in × $\frac{1}{4}$ in mild steel secured to the horizontal portion of the rest by bolts and wing-nuts and braced at their proximal ends by short strips of the same material hinged centrally to form an X and secured for ease of assembly by bolts and wing-nuts The two strips which form the horizontal platform of the splint are of different lengths and shape For the patient s comfort and ease of nursing the shorter side is placed nearest the perineum thus providing a splint for either the right or left side with the same basic material. The loop used for suspension of the foot or protection of the limb is of conventional pattern The provision of the extra pulley which converts the Braun splint for tibia to the Böhler-Braun type for femur is accomplished by the attachment of a further wooden horizontal section to the vertical portion of the original splint rest (fig 4)

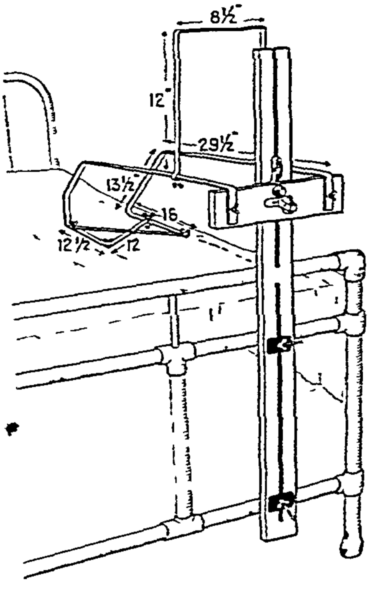

FIG 2—Components assembled as Braun splint for left side showing suspension or protection loop in position Addition of a further wooden horizontal section provides the extra pulley which converts splint into Bohler Braun type for femur

SUMMARY

A simple system of splinting for the lower limb is described This consists of a wooden rest for the Thomas splint, providing permanent fixation of the splint to the foot of the bed in the horizontal position at any desired height The method of converting this Thomas splint rest to either a Braun or Böhler-Braun splint is shown The system has technical advantages over the original types in addition to simplicity, portability and low cost

The original models of this system of splinting were made for me by Archibald Young and Son, Ltd , 57–61, Forrest Road, Edinburgh, 1

PHENYTOIN SODIUM (B D H)—An anticonvulsant for use in the control of epilepsy is available for oral administration in 1 g. tablets It is sodium diphenylhydantoinate, a derivative of glycolyl urea and an analogue of the barbiturates Its hypnotic effect is said to be negligible On beginning treatment with Phenytoin Sodium patients who are taking bromides or phenobarbitone should not stop at once these drugs but should gradually reduce the dose Mild toxic effects noted after the administration of phenytoin sodium include ataxia and vertigo, and treatment should be discontinued if a rash or pyrexia occurs After a long course of treatment gingival hyperplasia has been reported (*J Amer med Ass* 1939, 112, 1244) and vitamin C may be given concurrently to prevent this

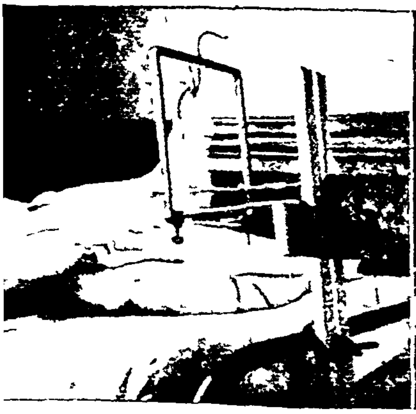

FIG 3—System in use as Braun type splint for a spiral fracture of tibia.

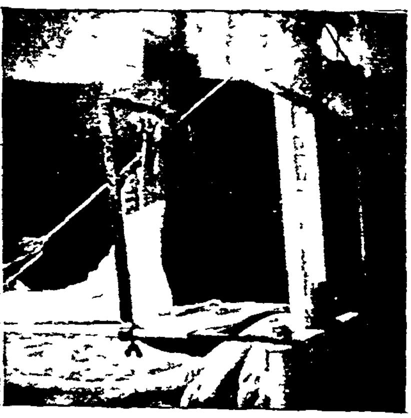

FIG 4—System in use as Böhler Braun type splint for fracture of shaft of femur.

[1] Mercer W *Practitioner* 1938 141 304 Smillie I S Thomson and Miles Manual of Surgery 1939 vol i, chap 30 p 583 Mackintosh's War Time Nurse Edinburgh 1940, 125

Hubert's (1926) case is interesting. A man was stung by a wasp at about 9 A.M. with no effects beyond the ordinary; an hour later he was stung again on the same arm. In 2 or 3 minutes he collapsed and became unconscious and when seen 20 minutes later he appeared about to die. He survived and developed an intense and general urticaria which subsided in a few hours without further ill effect.

Hubert attributes the symptoms following the second sting to sensitisation from the first; but to suppose that an anaphylactic state could develop in so short a time is against all experimental evidence. Although the symptoms in non-fatal cases bear so close a resemblance to anaphylactic shock it is difficult to believe that they are anaphylactic in the generally understood usage of the term. It seems that some explanation other than sensitisation or idiosyncrasy must be found for the fatal cases. Roch and others have suggested that the immediately fatal and the severe reactions are probably due to the chance entry of the venom directly into the blood stream. This explanation seems to meet the facts as well as any. Roch points out that dangerous reactions are particularly liable to occur when the site of the sting has a relatively thin covering of skin and is of high vascularity; as examples he mentions the temples, the back of the hand and the lips. In case 1 the sting was on the temple.

In this country there seems, in spite of obvious evidence, to be a reluctance to admit that the sting of one of the common *hymenoptera may sometimes* be the sole and immediate case of death. As pointed out as far back as 1862 by the Husemanns, this fact has medicolegal implications and demands recognition.

SUMMARY

Death may occur as the immediate result of a single wasp-sting. Two new cases are placed on record, and similar fatal results from the stings of bees are recalled.

All immediately fatal cases show an identical chain of symptoms preceding death; within 2 minutes of the sting the person collapses, consciousness is lost and he dies within half an hour. Subjects surviving for half an hour may show severe symptoms of anaphylactic type but always recover.

I wish to thank Mr Cyril Jones, of Wrexham, for drawing my attention to case 1, and to Dr Trevor Hughes and Dr G. R. Kennedy for details of cases.

PFEIFFER BACILLUS MENINGITIS

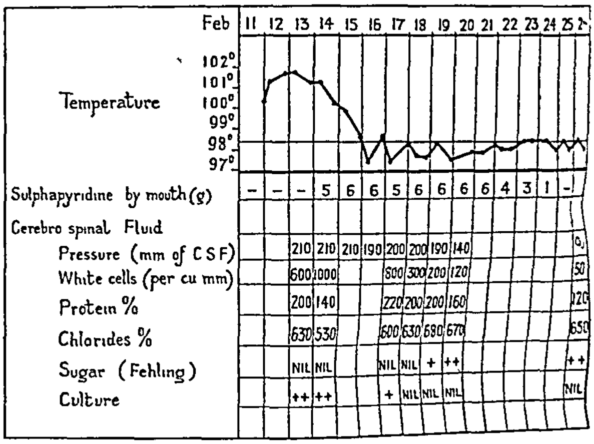
RECOVERY WITH CHEMOTHERAPY

JAMES T. HAROLD, M.B. Lond.
HOUSE PHYSICIAN TO THE MEDICAL PROFESSORIAL UNIT OF
ST. BARTHOLOMEW'S HOSPITAL, LONDON

MENINGITIS caused by Pfeiffer's bacillus (*Hæmophilus influenzæ*) is uncommon, and complete recovery from the disease is rare. In the case here described complete recovery followed the administration of sulphapyridine only.

A dustman, aged 59, walked into St. Bartholomew's Hospital on the afternoon of Feb. 11, 1941, complaining bitterly of headache. His illness had begun three days before, with sudden severe headache all over the top of his head. On that day he had felt sick and had three times vomited small quantities of food, but since then had not felt sick or vomited again. The headache got progressively worse and greatly interfered with sleep during the next two nights. The day before his admission he several times experienced giddiness on stooping, and his legs felt so weak that on three occasions he fell. He had no visual disturbance and had suffered no recent injury to the skull, although eight years previously he had sustained a fractured skull, and had subsequently accustomed to occasional headaches, especially he said he "had the 'flu."

On examination he was found lying on his side facing the light; he was somewhat drowsy but answered questions both coherently and cooperatively. Temperature 100.4° F., pulse regular with rate of 60, and respirations 24 per min. Both pupils were small but regular, the right being rather smaller than the left, and both reacted briskly to light. There was no neck rigidity. Kernig's and Brudzinski's signs were both negative. The tendon reflexes in both arms and legs were all present and normal, and both plantar responses were flexor. There was no herpes and both ears were normal.



Feb	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	2
Sulphapyridine by mouth (g)	–	–	–	5	6	6	5	6	6	6	6	4	3	1	–	
Cerebro spinal Fluid																
Pressure (mm of C S F)			210	210	210	190	200	200	190	140						9
White cells (per cu mm)			600	1000			800	300	200	120						50
Protein %			200	140			220	200	200	160						120
Chlorides %			630	530			600	630	680	670						650
Sugar (Fehling)			NIL	NIL			NIL	NIL	+	++						++
Culture			++	++			+	NIL	NIL	NIL						NIL

At first it was believed that he was experiencing an exacerbation of headache due to yet another attack of "influenza." During the next 24 hours, however, his headache got worse, and he could be seen clasping his head between his hands; he had not slept at all and seemed more drowsy. Although there was still no sign of neck rigidity, the physical signs remaining the same as on admission, it was decided to examine his cerebrospinal fluid. Lumbar puncture was therefore performed and 30 c.cm. of a faintly turbid yellowish fluid was withdrawn at a pressure of 210 mm. of C.S.F. The fluid contained 600 cells per c.mm., most of them polymorphs. A gram film of the centrifuged deposit revealed no organism, but culture on blood agar yielded a pure growth of a small, gram negative, rather pleomorphic bacillus, morphologically and culturally resembling Pfeiffer's bacillus. It was decided to treat the case with sulphapyridine, 2 g. by mouth followed by 1 g. four hourly, with daily lumbar puncture to reduce the pressure to approximately normal to relieve headache and provide drainage. He became afebrile within 48 hours of beginning this treatment (see figure), although culture of the C.S.F. was positive three days later. Clinically, his improvement was less striking; apart from temporary remissions following lumbar puncture his headache continued to trouble him with decreasing severity until eight days after treatment began, when it disappeared altogether. His progress proceeded satisfactorily and was marred only by the disturbing late appearance of neck rigidity nine days after admission—due to a carbuncle on the back of the neck, which also healed with treatment. In all, he received 54 g. of sulphapyridine without ill effect, his white cell count on Feb. 26 being 12,000 per c.mm. On the 23rd day after admission he was transferred to a convalescent home feeling well and without symptoms.

COMMENT

Pfeiffer bacillus meningitis occasionally follows disease of the middle ear, but usually it arises as a primary disease. The strain causing meningitis is believed to be distinct from those which commonly affect the bronchial tree, and may readily be distinguished from them by bacteriological means (Pittman 1931). Under the age of two years this type of meningitis is relatively common, Pfeiffer's bacillus then being the third commonest organism causing meningitis, following closely after the tubercle bacillus and meningococcus. It becomes progressively rarer with increasing age and is very uncommon in adults.

Up to 1930 the fatality, irrespective of age, was estimated by Silverthorne and others (1937) to be 98.0%. At this time there was no standard treatment; repeated bar punctures were usually performed, and a single very was recorded after intravenous colloidal silver tions Since 1935 most cases have been treated by method described by Fothergill, which consisted in sera and human complement administered both athecally and intramuscularly According to Lind- and others (1940), this method reduced the fatality 3% Since 1937 drugs of the sulphonamide group e been used in combination with serum and com- nent and the fatality has fallen to 54% (Lindsay l 1940) Treatment by chemotherapy alone has been often tried Teggart (1938) records complete recovery a man aged 60 after 63 g of soluseptasine, and e 9 cases have been reported in the English journals ecovery after sulphapyridine alone, although most of se were in young children Experiments recorded by obsen and Neter (1940) suggest that sulphapyridine he drug of choice

am grateful to Dr E F Scowen for permission to publish case, and to Dr B M Wright for carrying out the many hological investigations

LOOD AMINO-ACIDS IN HÆMATEMESIS

Douglas A K Black, M D St And, M R C P
BEIT MEMORIAL RESEARCH FELLOW
rom the Nuffield Department of Clinical Medicine, Oxford)

It has been known for some years that severe hæmorrhage to the stomach or duodenum is followed within a few urs by a notable rise in both the non-protein nitrogen d the blood-urea The raised values persist for 24–48 urs and then fall to normal, except in those cases here hæmorrhage continues or extreme limitation of the od and fluid intake leads to dehydration and exhaus- on The rise in the blood-urea nitrogen is sufficient to count for the greater part of the rise in non-protein trogen, but the amount of residual nitrogen (non- otein nitrogen less urea nitrogen) is sometimes large ough to suggest an increase in some other nitrogenous nstituent of the blood, the most likely being the ino-acids Moreover, in other types of extra-renal otæmia large increases of residual nitrogen have been ported (Nonnenbruch 1939) It was therefore decided determine the amino-acid nitrogen of the blood in a mber of patients with azotæmia secondary to gastro- odenal hæmorrhage

METHODS AND RESULTS

Amino acid nitrogen was estimated by the gasometric ethod (Peters and Van Slyke 1931), normal value 5–9 mg r 100 c cm, non protein nitrogen by the micro Kjeldahl ethod, normal value 25–50 mg per 100 c cm, and urea trogen by the urease and nesslerisation method (Archer and obb 1925), normal value 7–20 mg per 100 c cm

Observations were made on seven patients with æmatemesis In five they were made at the height of zotæmia, and again after recovery, except in one atient, who died within a few hours of admission, the esults are given in the table, cases 1–5 More frequent stimations were carried out on two further patients cases 6 and 7) The data in all seven cases show an ncrease in amino-acid nitrogen at the time of bleeding, he average being 15 2 mg per 100 c cm This increase s specially striking in view of the anæmia which most of he patients showed, since the amino-acid content of lasma is only about a fifth of that of the red cells Martens 1928), and one might therefore have expected ow amino-acid values in these anæmic patients It is oteworthy that the highest value found (20 mg per 100 cm) was in a patient (case 2) whose hæmoglobin was 6%, presumably blood dilution had not occurred by he time the sample was taken The amino-acid nitrogen ell as recovery took place, normal figures were reached n some of the patients before they left hospital, in others slightly raised amino acid nitrogen persisted into the recovery phase While there was a general correspondence between urea and amino-acid values, blood-urea was not necessarily highest at the same time as the amino-acid nitrogen

DISCUSSION

There can be little doubt that in the patients studied there was an unusually high entry of amino-acids into the blood-stream, not only from the mass of blood protein undergoing digestion in the alimentary tract but possibly also from breakdown of tissue protein (Black and Leese 1940) In health and in most diseases, however, the liver is well able to convert into urea any excess of amino-acids which enters the blood-stream, and little change in the amino-acid content of the blood follows the ingestion even of large amounts of protein Nonnenbruch (1939) believes that a raised blood-urea indicates renal damage, but that an increase in residual nitrogen, which includes amino-acid nitrogen, is due to liver dysfunction On this basis there would seem to be in our patients some degree of hepatic dysfunction The amount of hepatic impairment is no greater than could be accounted for by a mild degree of tissue anoxia The condition of the blood and circulation in patients who have had severe hæmorrhage is such that significant tissue anoxia is probably present in all the organs, and there is objective evidence of cardiac muscle anoxia in the electrocardiographic changes described by Aschenbrenner (1934) The small degree of impairment of hepatic function is particularly striking when compared with the severe renal impairment which is suggested by the high blood-urea, and demonstrated by the fall in urea and inulin clearance (Black et al 1941)

The explanation of the very different extent to which hepatic and renal function are affected seems to lie in the arrangement of the circulation to these organs The liver receives its main blood-supply at a comparatively low pressure from the portal vein, and all the blood coming from the intestine has to pass through it, it is therefore little affected by fall in systemic blood-pressure, and amino-acids absorbed from the bowel are exposed to deamination in the liver before entering the systemic circulation On the other hand, the efficiency of glomerular filtration depends greatly on the state of the systemic circulation, Powell, Smith and I (1941) have shown that the renal insufficiency in hæmatemesis is largely due to a fall in blood-volume and blood-pressure leading to a diminished circulation through the kidney

SUMMARY

The amino-acid nitrogen of the blood has been determined in seven patients with azotæmia secondary to gastroduodenal hæmorrhage, and was found to be increased

The increase probably indicates hepatic dysfunction, though this is slight compared with the renal impairment which can be demonstrated by other methods

which the patient came back with all his former symptoms Resumption of thyroid treatment was again effective

DISCUSSION

The differential diagnosis between this syndrome and that described as angina pectoris vasomotoria of vagotonic origin deserves consideration The symptoms and some of the signs of the latter are similar to those found in cases 1, 2 and 3 above In angina pectoris vasomotoria, the left ventricle is often dilated in a rounded or pointed manner and the patient has a tendency towards bradycardia, and a low blood-pressure with cold extremities and pallor (pseudo-anæmia), the capillaries appear normal, however, in most cases Electrocardiography sometimes shows low waves and prolonged P-R intervals The B M R, too, may be decreased, I have found values as low as −30% in such cases Characteristically the values oscillate considerably, in contrast to those found in hypothyroidic patients In collaboration with Dr Kaatz I obtained the following values at intervals of 4 weeks,

Case 4	Case 5	Case 6
−12 6%	−17%	−30%
−30%	−3%	−13%
Normal	−22%	−10%

Patients with the syndrome I have just described so show a dilated heart with a rounded or pointed left ntricle, a tendency to bradycardia and a low blood-essure, the heart sounds are soft The electrocardioam is often normal, but in some cases shows changes milar to those found in myxœdematous patients The M R is abnormally low, the circulation time usually olonged, and the blood-cholesterol level high Thus, e circulatory system regularly shows some but not all the typical signs of myxœdematous heart We may erefore speak of an "abortive myxœdematous heart" this condition symptoms subside on administration thyroid (0 5–0 6 g thyroideum siccum weekly), us should be discontinued as soon as tachycardia evelops and resumed only if bradycardia recurs The ypofunction of the thyroid gland causes decreased mpathetic action on the heart and a resultant increase the vagal action. Primary vagotonia, as we have en, produces angina pectoris vasomotoria, which is in any respects similar to the hypothyroid syndrome It difficult, therefore, to decide whether symptoms are aused by a primary vagotonia or by relative vagotonia esulting from hypothyroidism, and at times it can only be ettled by the therapeutic test—that is, by giving thyroid

In case 2 the differential diagnosis was made easier by e history that the patient had previously suffered from raves's disease, had recovered completely and then swung o the opposite extreme, developing an abortive myxœdematous heart The transformation of Graves's disease into yxœdema has, of course, often been reported by myself nd others (Zondek 1923b)

Drugs depressing vagal action may also have a good ct in hypothyroid heart cases because of the relative otonia present Complete success, however, can only obtained with thyroid Thyroid acts, I think, by ucing the tissue-fluids, and thus dehydrating the rt muscle In 1918 I demonstrated that the fluid tent of myxœdematous heart muscle is abnormally ; this has been confirmed by Webster and ke (1936) Lately, in coöperation with Kaatz and hael, I have been able to prove that the capillaries hypothyroid patients are usually very narrow, with circulation In some cases only the loops of the illaries are to be seen in the form of small hooks, while limbs are completely invisible It seems that the ssure of the increased tissue fluids compresses the llary walls, causing deficient blood-flow The illaries gradually become normal under the influence thyroid It is reasonable to suppose that similar nges occur in the heart vessels and that thyroid roves the cardiac circulation, relieving symptoms by ydrating the heart muscle and easing the pressure on small vessels supplying it

he favourable effects of thyroid on patients with inal symptoms have special interest in view of the ommendation, made recently, of thyroidectomy in the atment of angina pectoris Cases of angina pectoris ch improve on partial thyroidectomy represent a syndrome fundamentally different from that described in this paper. The pathological process, in such cases, is sclerosis of the coronary vessels, if the thyroid hormone is eliminated there is a decrease in sympathetic tonus, and thus probably a decrease in the oxygen requirements of the myocardium and in the work of the heart Thyroid therapy in such cases may produce an increase in symptoms This may also occur occasionally in myxœdematous patients, especially after prolonged thyroid administration, since arteriosclerotic changes of the vessels are not at all rare among the middle-aged Thus the causes of anginal symptoms in cases with fully developed or abortive myxœdematous hearts may be various.

SUMMARY

The possibility of hypothyroidism must be kept in mind in treating patients with anginal symptoms Precordial distress and substernal pain, collapse recurring more or less frequently and accompanied by pallor, considerable fall in blood-pressure, bradycardia and a small pulse seem to be characteristic of the condition. The circulatory system shows signs typical of true myxœdematous hearts—cardiac dilatation of varying degree, a tendency to bradycardia and low blood-pressure In some cases the electrocardiogram shows changes corresponding to those found in myxœdema (flattening of P and T waves, negative T wave) in other cases there are no abnormal findings The peripheral vessels (capillaries) are narrow and circulation is slowed The basal metabolism is decreased, the blood-cholesterol level high (values as high as 400 mg per 100 c cm have been recorded) High blood-cholesterol is characteristic, and is often the earliest sign of the disease, as it is in fully developed myxœdema An increase in tissue fluids including those of the myocardium, leads to a secondary compression of the small cardiac vessels causing an "imbibition angina" Therapeutically small doses of thyroid (0 5–0 7 g weekly) are effective as a rule The treatment should be continued for several weeks with short interruptions, and should be repeated when bradycardia reappears Thyroid probably acts by dehydrating the heart muscle The cardiovascular syndrome here described may be designated "abortive myxœdematous heart" The ordinary vagal heart (primary vagotonia) may be accompanied by symptoms and signs similar to those of the condition described. The symptoms of such patients subside on administration of drugs decreasing the vagal tonus or causing vasodilatation (calcium, papaverine, atropine, diuretin or small doses of phenobarbital)

INTESTINAL DAMAGE FROM A SMALL WOUND

L A LEDINGHAM, M B Aberd
ASSISTANT MEDICAL OFFICER AT PADDINGTON HOSPITAL (L C C)

THE following case was one of many air-raid casualties admitted to hospital on the same night

A married woman, aged 27, was admitted from a bombed building within ½–1 hour of the incident She had heard "something coming down" (a very large high-explosive bomb) and had quickly lain down prone Immediately after the explosion she felt a pain in the abdomen On admission to hospital she was pale and a little shocked, pulse rate 80, fair volume, respirations normal but with limited abdominal movement, temperature just under normal She complained of abdominal pain, generalised but of only moderate severity, and there was slight tenderness and rigidity One minute wound about ¼ in long in the right buttock just above the tuber ischii was the only external trauma visible The patient was unaware of this and no point of entry in her clothing has subsequently been found She was obviously badly frightened by the experience and a bromide and chloral sedative was given and shock treatment instituted After 1½ hours, in view of persistent and increasing abdominal pain and in spite of a steady pulse, it was decided to explore the abdomen At that time the abdomen was slightly rigid and very tender, moving poorly, liver dullness was present and no free fluid was definitely identified

Under gas, oxygen and ether anæsthesia a small para-umbilical incision was made Blood and fluid and solid fæces welled into the wound In all 16 entrance and exit wounds were found at intervals of about 8 in along the small gut with characteristic pouting mucous membrane, each oozing bowel contents and blood The largest admitted two fingers and the majority were ½–¾ in across One or two of the in and out wounds were confluent where the bomb casing had bitten out the antimesenteric border of the bowel and one perforation involved the mesentery as well as the adjacent bowel A solitary perforation of the lower sigmoid colon discharging solid fæces was also present The various perforations were repaired as rapidly as possible in the transverse axis of the gut by two layer inverting eyeless-needle sutures and after evacuation of the bulk of the free blood and intestinal contents, inspection of the liver and palpation of the spleen and left kidney the abdomen was closed with pelvic tube drainage Nothing more was done beyond the application of a small dressing to the entrance wound The repair took about 1½ hours

She was given a small blood-transfusion and for 4½ days subsequently fluids were supplied by intravenous drip (saline glucose 5%), only small sips of fluid being allowed by mouth -Morphia was given liberally Prophylactically, M & B 693 soluble (intravenous) was given via the drip tubing, one ampoule 6-hourly for 4 days

The bowel remained silent and apparently completely inactive for 4½ days No colic was felt and no flatus and only minor postoperative vomiting was noted On the 5th day there was slight distention and much flatus was passed The drainage tube which was removed after 48 hours left a track from which sero pus containing *Bacillus coli* cont to drain for 3 weeks Feeding was started on the 5th with citrated iced milk and, for want of oranges, rhu juice, which she tolerated well as opposed to sweet d On the 14th day evidence of a pelvic collection—diarrh and a tender mass in the pouch of Douglas with fixation the pelvic organs—was discovered, and signs of deep sup-puration in the buttock were evident Opportunity was awaited to open the pelvic abscess per vaginam but 3 days later the buttock wound discharged about ½ pint of pus and the pelvic inflammation started to resolve A threatened obstruction with visible peristalsis and distention evidently centred about the terminal ileum also resolved along with the pelvic condition and may have been due to ileus duplex

Now, 4 weeks after the original injury, she is getting about fairly well in the ward and eating ordinary diet Occasional very mild colic and a feeling of being lost without her manytail binder are her only complaints

This case seems to emphasise the importance of small wounds in war surgery where vital structures can be badly damaged by minute particles of high speed shrapnel In this case the shrapnel is still lodged in the left perirenal area having reached there via the right buttock right iliac bone, large gut, small gut and posterior peritoneum Her recovery is due to (1) careful examination by the receiving room staff with denial of morphia, (2) a well-given anæsthetic under difficulties, (3) unremitting aftercare by nursing staff and students, of whom the latter spent many sleepless nights attending to the case, and (4) morphia and intravenous saline which allowed the gut to rest and heal

I am grateful to Mr G M Gray, medical superintendent, for permission to publish the case

Reviews of Books

Macleod's Physiology in Modern Medicine

(9th ed) Edited by Philip Bard, professor of physiology at the Johns Hopkins University London Henry Kimpton Pp 1256 50*s*

Eight principal and three subsidiary authors (one of whom, W S Root, is not mentioned on the title page) have contributed to this book The sections on the nervous system (Philip Bard), the circulation (H C Bazett), respiration (C F Schmidt), the distribution and regulation of water and the kidney (M I Gregersen) are very well done, and in parts outstanding H J Curtis's lucid treatment of excitation and the nerve impulse is fully in keeping with the high standard of the section on the nervous system The special-sense section (J M D Olmsted) is adequate for medical students, but superficial in parts The subject of metabolism and nutrition, admittedly one of great diversity, receives a somewhat patchy treatment by C L Gemmill He begins well, but tends to tail off into the style of a review in which many findings are mentioned to the detriment of the exposition of fundamentals, the style becomes too hurried for a textbook G R Cowgill's chapters on the alimentary tract are sound, placid and dignified, but would be improved by more illustrations and tables The endocrine glands, and what there is about reproduction, are dealt with in 68 pages by R G Hoskins, and the exposition is clear The space accorded to these subjects in textbooks of physiology is traditionally small, but it is disappointing to find it still restricted in a book which is above all things modern A lesser example of lack of balance is seen in the 19 pages devoted to coagulation of the blood (3 in small print on clinical aspects) as against 5 on the urinary bladder Nevertheless this is one of the best of modern textbooks of physiology It contains upwards of 2000 references to original literature and authoritative sources, the table of contents is exhaustive, the index good, and it is beautifully produced and strongly bound The pale green tint of the pages is congenial to the eye

Williams's Obstetrics

(8th ed) By H J Stander, M D, F A C S London D Appleton Century Pp 1401 55*s*

In 1934 Professor Stander revised, and thus rejuvenated, the last edition of Dr Whitridge Williams's textbook of obstetrics, which on its own merits ranked as the premier reference textbook in obstetrics in the English language The new edition is completely rewritten and little of the original text remains, though the form is to some extent retained For sentimental reasons it is still called "Williams," but is in fact almost pure Stander The illustrations and diagrams are excellent and it covers every aspect of its subject The final year student can read and enjoy it, but its chief appeal will be to the more advanced practitioner who intends to specialise in obstetrics At the end of each chapter there is a generous bibliography in all languages The classification of the toxæmias of pregnancy will not, perhaps, be acceptable to British obstetricians—and so much the better The chapter on radiological pelvimetry is an eye-opener and shows us up badly in this country, it should be read by all who propose to perform measurement of the female pelvis by radiography Every English obstetrician who wishes to broaden his views beyond the orthodox and accepted teachings of his own school will value this as the splendid book it is

Pharmacological Basis of Therapeutics

By Louis Goodman, M D, and Alfred Gilman, Ph D assistant professors of pharmacology and toxicology, Yale University school of medicine London Macmillan and Co Pp 1325 50*s*

This is one of the most comprehensive books at present available on pharmacology from the clinician's point of view The material offered to the reader is inevitably much the same as in other detailed works on the subject, but the presentation is different in several important particulars By sifting the many doubtful theories which have gained credence through frequent repetition the authors have made the subject more reasonable and therefore more readable than usual References to original work are included, but no attempt has been made to give exhaustive abstracts of the literature, examples serve the main purpose of the book—to illustrate the application of drugs in medical treatment They discuss drugs according to the system of the body on which their action is greatest This is natural, having regard to the therapeutic approach which has been adopted, but they have evidently shared the experience of other writers in finding the heavy metals, the vitamins and the gases an awkward squad to classify Toxicology is dealt with in unusual detail, but is carefully correlated with pharmacological action There is a useful appendix on prescription writing for the student

THE LANCET

ONDON SATURDAY, SEPTEMBER 13, 1941

FIRST-AID FOR EVERY SOLDIER

With the open order attack of the British Army as devised in the Sudan, developed in South Africa, practised on Salisbury Plain and used in mobile warfare during the last war by regulars in the battle of the Marne and by territorial and dominion troops in Palestine later, there were two possible views as to the tactical use of field-ambulance stretcher-bearers One was to keep them back so that they would not be wounded and have to be carried off by their fellows who should be stretchering wounded combatant troops The other was to keep them right up behind the supports where they could get to work on the wounded at once, and where the combatant troops going into action would see them and know that if they were hit they were certain of being given first-aid quickly Of the value of this to morale there can be no doubt Time may change the superficial appearances of war as of medicine, the principles that underlie both are immutable, and the principles of medicine say that first-aid must be immediate and those of war say that the man fights better if he knows he has a chance if he is hit But today there is no front line, no firing line to be built up by the incorporation of supports behind which the stretcher-bearers can advance and pick up wounded as they fall. There are little pockets of men all over the place—France, Greece, Russia, tell the same tale—and if the man is to get first-aid he must get it from his mates An unnamed lance-corporal of the line wrote this in The Lancet of Feb 15 (p 231)

Soldiers expect to take risks, but some of the men with whom I served in France need not have died and many more are today minus limbs who might still be whole One of the important lessons we learned in France was the prevention, as far as possible, of serious casualties A wounded soldier is a liability to himself and everyone else, and practical first-aid should be included in a recruit's syllabus A soldier is taught how to kill and destroy how to operate and fire his weapons and the best way to protect himself against similar weapons, but not one lesson does he receive on how to save his comrade's life

And now there comes a soldier-doctor to tell how it should be done Mr Charles Keogh was a combatant in the last war and became a medical student after it Thus he knew the soldier, knows what he needs, and knows how to give it him He has produced a card called 'First-aid for Fighting Men'"[1] which contains—in twenty brief paragraphs and ten striking sketches—all that the fighting man *need* know of the subject 'First-aid saves lives and stops panic' he says, a principle of medicine which combines the physical with the mental "A lightly wounded man if given first-aid, can go on fighting", a principle of war which says that the first duty of the doctor is to keep men fit and fighting Of a badly wounded man he writes "Treat him like a child Calm him Calm the men in your post This is first-aid" There is beauty in this, the beauty of experience and of the mind that in tending one does not forget others, and finds the two the same "Any fool can be brave and get killed, be brave and don't get killed, and save your friend instead' Brave words and true "A man bleeds to death very quickly. Stop it with your hands There is no time to wash' A rigid coherence to the formalities of operative technique is far too often insisted on in teaching these things today "Give any wounded man a drink of anything you have—but do not give a drink to a man with a wound in the belly, or to a man who cannot swallow You will kill him if you do" We do not yet know what shock is, but no-one has put what we do know better than this. "Shock kills more men than bullets Shock is a mixture of pain, fear and cold Do what you can to stop all three Shock kills brave men" The card ends with "Courage in disaster Courage in the presence of a wounded man First-aid can save a situation and save a friend."

This card, if adopted by the Army, should be issued not to every man but to every subaltern with the responsibility of seeing that every man under him knows it by heart. It is for the Adjutant General and the Army Council to decide whether they will take the advice of the nameless lance-corporal and make the rehearsing of its simple precepts part of the training of every soldier

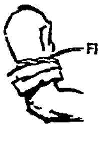

FIG.2

8 IF YOU CAN'T STOP IT that way slip a piece of string round the leg or arm higher up A pull through or sling will do tie it over his uniform Tie one knot (fig. 2) Put a pencil or piece of wood on the knot (fig 3) Tie twice over the stick Tie a reef knot. Tie any knot if you don't know how (figs 4 & 5) Twist the stick until the bleeding stops. Keep it in position by tying the ends down (fig 6) This is a Tourniquet.

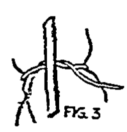

FIG.3

9 A TOURNIQUET can save a life and a limb. It can also kill a limb. Loosen a tourniquet every quarter of an hour Four times an hour If you don't, the limb will die

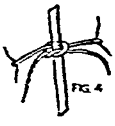

FIG.4

10. IN WAR, a wounded man may be hours or days before he gets to a Surgeon. If ever you put on a tourniquet, put a label on. Write "Tourniquet applied 9 a.m. Tuesday" Loosen four times an hour Tighten again if bleeding starts. Fix the label where it can be seen (fig 7)

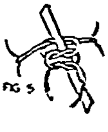

FIG 5

11 BROKEN BONES Place the limb in it's most natural position and you can't go wrong Don't let a broken limb flap. Sharp ends of broken bone can cut arteries and nerves to pieces. Tie a broken arm to the chest with any kind of bandage. But tie it firmly (fig. 8) Tie a broken leg to the other leg. Use as many bandages as possible Foot to foot, knee to knee thigh to thigh (fig 9)

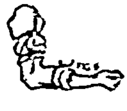

FIG 6

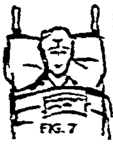

FIG.7

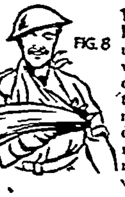

FIG.8

12. CARRYING A WOUNDED MAN under fire Keep under cover Tie his wrists together Crawl on hands and knees on top of him Put your neck under his wrists and drag him along underneath you. You can go miles this way and you will not give away the position of your post to the enemy (fig. 10)

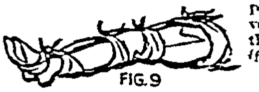

FIG.9

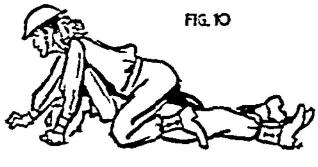

FIG.10

13. SMALL PUNCTURED WOUNDS are often more dangerous than dreadful bloody ones. A spent bullet from the air can go right through a man Punctured wounds must be seen by a Doctor

HEPARIN AND A RIVAL

WHEN CHARLES and BEST in Canada and JORPES in Sweden purified heparin sufficiently to enable it to be given intravenously to patients, they opened up a wide field of possible therapeutics Could we, by rendering the blood less coagulable in vivo, control those processes of embolism and thrombosis that are so difficult to treat ? Would heparin help in operating on blood-vessels ? Were patients liable to serious hæmorrhage when heparinised ? The progress made in Sweden was described by various workers at a symposium on heparin held at Stockholm in December last [1] There was general agreement that heparin is most useful in the treatment of thrombosis of the leg veins, in operations on blood-vessels such as embolectomy, and in the prevention of postoperative thrombosis and embolism It is now clear that eparin cannot influence a thrombus once it has ormed, but if the onset of thrombosis can be detected at a very early stage the process can be aborted by heparinisation of the blood, BAUER [2] finds the classical clinical signs of early thrombosis very unreliable and he uses "venography"—radiographic outlining of the veins after injection of iodoxyl—to ecide whether thrombosis is beginning or how far has progressed Good results cannot be expected m heparin treatment if the thrombosis has spread o the thigh veins and especially if the femoral vein is involved If the case is suitable, he gives 100 mg intravenously three times daily until the pulse and temperature have returned almost to normal, this takes 4–7 days and he then allows the patient to get up He reports 21 cases successfully treated in this way LINDGREN and WILANDER [3] record the use of heparin in 8 operations on blood-vessels, 200–300 mg divided into four intravenous injections was given daily for 4–15 days and good results were obtained in all cases

The value of heparin as a prophylactic against postoperative thrombosis is more difficult to assess since these accidents are fortunately not common CRAFOORD and JORPES [4] selected a group of 325 patients all over 30 years of age who had to undergo operations more specially liable to thrombo-embolic complications, such as those on the appendix, gall-bladder, stomach, or male genitalia They were given regular heparin injections beginning 4 hours after the operation and continuing for 5–10 days Four intravenous doses of 50, 50, 50 and 100 mg were given every day, with an interval of 4 hours between each, in some cases the dose was increased At the end of heparinisation the dose was diminished gradually, because after sudden withdrawal pulmonary embolism sometimes occurred 10–15 days later No complications were recorded in these 325 patients As a contrast, over the same period 302 similar cases were operated on without heparinisation, 33 (11%) had definite thrombo-embolic complications and 9 died, in a control series of 809 similar cases from a previous period the incidence of thrombosis and embolism was about the same Treatment after thrombosis has occurred is far less satisfactory, in some patients there was considerable subjective relief and pulse and temperature rapidly returned to normal, but in many others there was no clear effect According MURRAY,[5] similar conclusions and results on all points have been obtained by Canadian workers, they prefer to give the heparin in a continuous intravenous drip instead of in separated intravenous doses

Heparin is non-toxic and can be safely given hours after a surgical operation or 24 hours after delivery in obstetrical cases, should excess bleeding occur it can be controlled by a small blood transfusion or injection of protamine sulphate But it is unfortunately difficult to make in quantity—the source is ox lung or liver and the yield is small—and it is therefore expensive Patients with venous thrombosis suitable for heparin treatment are not common, and embolectomy operations are distinctly rare, so that hospitals might be able to bear the expense of individual cases of this sort, but the prophylactic use of heparin involves the treatment of hundreds of patients At present rates the minimum prophylactic course costs about £6 (plus purchase tax) the hospital makes its own sterile solution from the dry powder and much more if the heparin solution must be bought This is obviously *not practicable* however desirable and MURRAY *hopes that some* equally non-toxic substance *with similar properties* will be found that is less expensive BUTT, ALLEN, and BOLLMAN [6] suggest that a substance with the desired properties has been found in 3,3' methylene bis-(4-hydroxycoumarin) This compound is chemically quite different from heparin *It* was originally found in hay or silage made from the common sweet clovers which had been improperly cured, this is known to cause a hæmorrhagic disease in cattle K P LINK of the University of Wisconsin and his associates isolated the hæmorrhagic agent of spoiled sweet clover and have succeeded in synthesising it Preliminary work has shown it to be non toxic in human patients It greatly prolongs the coagulation and prothrombin times of the blood but takes about 48 hours to develop its effect, but when the effect is fully developed, it is lasting It seems best to give it in a series of divided doses and it has the enormous advantage of being active when given by mouth in gelatin capsules Its effect can be rapidly checked by a small transfusion of normal blood This substance should be relatively cheap, and it may make general preoperative prophylaxis a practical possibility Let us hope its discoverers will think of a shorter name for it, preferably one that will recall its pastoral origin

NURSING RECONSIDERED

ENGLISH nursing is falling off for la candidates for training—not merely of s candidates, but of sufficient candidates of an The high standards set by the nineteenth pioneers can only be maintained if the best i woman in the country is willing to take up ni That the cream of our public and secondary girls—young women of character and promis present choose other callings in preference to n cannot be said to reflect on the girls They plenty of interest in public welfare, applying ir numbers to train as social workers, though ap ments for those who qualify are scanty, mor st women have an instinctive bias which makes h nursing as comes their way congenial When attractive occupation is neglected the fault must in the terms of service.

[5] Murray, G D W Brit J Surg 1940, 27, 567

[6] Butt, H R, Allen E V and Bollman, J L Proc May June 18, 1941, p 388

The establishment of a nursing division at the nistry of Health is evidence that remedies are ing sought and organisations up and down the untry are making suggestions One proposed state heme of training for nurses has lately been drawn p as a basis for discussion by the Manchester public-ealth department in which a plan is set out whereby e nurse might obtain basic general training. and also ecialised training within a period of four years wise proposal is that schools of nursing should be ttached to the universities so that student nurses ould have the same standing as students taking a iploma in social science This would go far towards ringing a nursing qualification into line with other academic and technical diplomas At present only two English universities, Leeds and London give diplomas in nursing in painful contrast with the copious references in the index of the Universities Yearbook to nursing diplomas in Canada and South Africa Special training for assistant nurses is also suggested in the Manchester scheme either in the form of a modified course in hospital, with examinations in practical nursing or as a special course at approved institutions If a second grade of ward helper is essential—and in the present straits she certainly is—it is wholly desirable that she should have a defined training and clearly specified duties she may then prove to be a reliable and even indispensable member of her profession But it seems at least equally important that she should be designated by some title other than that of nurse A constructive scheme based on wide inquiry has lately been outlined[1] by four members of the nursing profession who may justly speak with authority—Miss E C. EARCE Mrs B A. BENNETT Miss L SNOWDEN nd Miss G B CARTER They accept the principle at two grades of nurse have become necessary d suggest that students training for grade I ndard should hold the school-leaving certificate a higher qualification and should be in training 4½ years Grade II students would be drawn secondary or elementary schools and need hold ertificates their training would last 2½ years inating in an examination largely practical and They suggest the descriptive term sister he first, and nurse for the second grade to diminish the title of nurse seems unfortunate . y it should be kept for the state-registered woman the term student nurse for the woman ding to qualify For a helper of the second some other description must be found (e g lla) to call her a nurse—even an assistant —is to debase the currency of nursing and to e confusion in the minds of the public

e Manchester suggestions are timely, but they at nursing from within If recruitment is to nproved it is essential to look at the profession gh the eyes of the recruit and it is inept to say er The welfare of the patient must be the first uderation The nurse must be prepared to sacri-herself to that An appreciation of the patient s ns can only develop fully in a woman who has begun to study nursing and to love her calling A demand at the outset for sacrifices only alarms the hesitant · and in any case no more sacrifices should be required from a student nurse than from any other young person studying for a profession Few careers in medicine fail to include a sense of vocation but how many deans of medical schools find themselves extolling sacrifice to prospective students ? It is not at the outset a question of money · students in professions other than nursing expect to pay not to be paid At the beginning of this year the Minister of Health tried to overcome the shortage of applicants by raising rates of pay and by appealing for more nurses The rates of pay in the Civil Nursing Reserve were set at £40 a year for student nurses £105 for trained nurses £55 for nursing auxiliaries and £70 for assistant nurses in all cases with board lodging and laundry allowed There are objections to this arrangement . at present most auxiliaries and assistant nurses are only partly trained women who for one reason or another are not attempting to become state-registered nurses They are living in close association with student nurses and—though having a somewhat lower status—are receiving higher salaries The establishment of two grades trained for different purposes would help to overcome this difficulty It might then become possible to treat student nurses as true students and pay them nothing · but in that case the hospital should cease to depend on their labour for the care of patients They should be like medical students an accessory not an integral part of the staff To run hospital nursing largely on student labour as is done at present is unjust both to the trained nurse and the nurse in training It limits the number of posts open to trained women and subordinates the interests of the student to hospital convenience If she is being paid for service at however inadequate a rate the nurse is in a weak position to argue her cause as a student.

The salaries to trained staff are moderate when all emoluments are reckoned in but part of these emoluments take the form of board and lodging. and the trained nurse is thus compelled to live in hospital —a plan which makes for hospital convenience and economy, but has serious side-effects for the nurse Few people. male or female benefit by living in a circumscribed world composed largely of their own sex , maturity of the mind and emotions is difficult to achieve and maintain in such surroundings Intelligent girls contemplating the profession feel that nurses should have at least as much private liberty as women doing say secretarial work . and that they would be the better for it Nor are the prospects for the older nurse outside hospital such as to inspire confidence in parents seeking a safe livelihood for their daughters or in the daughters themselves In private nursing the young nurse is often prized above her seniors District and school nursing, though giving a measure of freedom are hard exacting jobs and not particularly well paid Mental nursing is interesting work and pensionable but the isolation of many mental hospitals and the need to live in (as well as that uninformed dread of mental patients which is almost universal) deters many · while the higher rates of pay offered attract those who are driven rather by their financial needs or responsibilities than by an interest in mental work

---

[1] Nursing Mirror Aug 23

The logical way out of the recruiting dilemma is to ask the girls themselves what they want and to pay some attention to the answers These are reasonable enough they want equal freedom and leisure with other girls in training, prospects of a safe and adequate livelihood, and an opportunity, when training is complete, to live a normal home life outside working hours And if they cannot get these things they will not flock to become nurses it is as simple as that The national committee on nursing which the Minister of Health contemplates setting up is to have panels representing employers and employed It might be as well to add a third panel composed of parents, headmistresses and possibly of girls leaving school—or at least to hear evidence from these interested and interesting parties A real appreciation of fundamental issues appears in the scheme drafted by Miss **PEARCE** and her colleagues, and also in a bill on nursing lately drawn up by the Women's Parliament, at their first session on July 13 last This bill asks for reorganisation of the training system so that students should not required to perform full hospital duties simultaneo with their studies, for a forty-eight hour week, four weeks holiday annually for student nurses five weeks for trained nurses, that trained nu shall be allowed to live outside hospital and to continue their employment after marriage, and that nurses' homes for those in training shall be run as hostels, controlled by an elected committee of the residents There are other suggestions, about rates of pay, pensions, uniform and the training of nursing auxiliaries; but those set out above strike at the heart of the difficulty They are precisely those which the hospitals find it hardest to face, because they alter fundamentally their disciplinary and economic relations with the nursing staff If the best types of woman in the country, however, are unwilling to submit themselves to the traditional conditions, the conditions must give way We not only want the best nurses we can have them—but on contemporary terms

Annotations

INTRACAPSULAR FRACTURES

NEARLY 40 years ago Royal Whitman of New York began to teach that fractures of the neck of the femur—which for many generations had been regarded by surgeons as a lost cause—could be reduced by manipulation, and, if fixed in a plaster spica with the hip abducted and extended, could be expected to unite soundly In due course Whitman was able to demonstrate to unbelievers that the abduction plaster could be used with safety in old and frail patients This was a notable landmark in the evolution of modern fracture treatment, and the Whitman procedure soon became the accepted routine in surgical clinics throughout the world As experience increased, it became evident that there were many disappointments and failures still to be faced, even in experienced hands, and in recent years, the treatment of this type of fracture carried with it a mortality of 12–15%, and bony union was observed in not more than 50% of the cases In 1907 Pierre Delbet of Paris had devised an operation in which the fracture line was transfixed in the long axis of the femoral neck by a screw or nail, the whole procedure being carried out under X-ray control The Delbet technique attracted few followers, and it was not until 1931 when Smith-Petersen[1] of Boston reported the first series of cases in which he had used his now famous triflanged nail, that interest was reawakened in the problem of internal fixation of the fracture Smith Petersen's mode of attack was to reduce the fracture after exposing the fragments through an anterior arthrotomy, and to insert the nail under direct visual control The disadvantages and risks of a wide exposure of the hip-joint in the older patients led to a revival of the Delbet principle of nailing under X-ray control. Since 1934 this principle has gained almost universal approval, and the triflanged nail provided with a central canaliculus to allow its insertion over a guide, has been used in the majority of surgical clinics In the perfection of the technique of extra articular nailing, Sven Johansson of Gothenberg[2] and Thomas King of Melbourne,[3] amongst others, have played a notable part

In the United States, multiple wires of the Kirschner type have found favour as an alternative means of internal fixation, and more recently the advantages of a special screw so constructed as to exert a binding or impaction force on the fragments, were stressed by the late Vittorio Putti[4] in one of the last contributions made by this great intellectual leader of orthopædic surgery Some of the earlier reports of the results of extra articular nailing, which were based on comparatively short periods of observation, created the impression that the problem of the intracapsular fracture of the femoral neck was now finally solved But evidence which is now becoming available shows that this optimistic view is unjustified A valuable report of a commission set up by the American Academy of Orthopedic Surgeons[5] has been recently issued, the commission has analysed the late results of pinning in 247 subcapital and transcervical fracture, which—out of 923 documented cases—were accepted as fulfilling the following requirements the fractures were recent and showed definite displacement, pre reduction and post reduction radiograms were available for scrutiny, and radiograms of the fracture taken one year later accompanied the clinical notes In these 247 cases the fracture was secured by a triflanged nail in 144, by multiple wires (pins or spikes) in 83, and by miscellaneous means (screws, grafts) in 14 The commission found that bony union was obtained in 169 cases (70 1% with a slightly higher figure in fractures treated by the triflanged nail as compared with those fixed by multiple wires Arthritic changes of varying degree developed in a quarter of the cases in which bony union occurred, the most severe types of arthritis, which were characterised by aseptic necrosis and disintegration of the femoral head, were seen in cases examined 18 months and 2 years from the time of the operation In the non union gro (30%) there was a higher incidence of failures in fractures imperfectly reduced

The 923 cases (of which 682 were rejected in the sum of late results) yielded valuable collateral information The mortality was 11 6%—not very different from the figures for the Whitman method Failure to maintain fixation of the fragments, owing to breaking of the nail or shifting of the nail, was reported in 11% of the triflanged nail cases, in 21% of the multiple wire cases and in 2 of the cases fixed by miscellaneous means It was not that a shifting nail tended to be extruded when multiple wires tended to enter the joint cavity De these drawbacks the commission were in no doubt th in the hands of expert surgeons the modern method internal fixation had improved the results of the tr ment of intracapsular fractures of the femoral ne ey concluded with a note of warning—that many appointments and failures were bound to occur if the ethod was used by inexperienced operators

There is as yet no comparable series of documented ses treated in Great Britain but a recent analysis of the te results of 75 consecutive intracapsular fractures eated in the Bristol fracture clinics[6] bears out the utious findings of the American observers In the istol cases which were all reviewed after one year or nger bony union (demonstrable by radiography) was btained in 58 7% necrosis of the femoral head eveloped in 14 7% (it was commoner in the younger atients) the operation failed for technical reasons in % and the mortality (within three months) was 3% Clearly the intracapsular fracture of the neck f the femur still presents a formidable problem

A BOOK ON BURNS

The flash of the exploding bomb fire in the air fire on the ship the burning house all the associates of war make burns one of the most important of war injuries Before the war we accepted the tannic-acid treatment of burns rather as the totalitarian states accept the dictates of the dictators—en masse Every wrinkle every finger every eye every degree of burn required only this one treatment The pace of war quickened the burns were severe and the misuse and maluse of tannic acid was soon to lead to some tragedies Then the pendulum swung to the opposite extreme and tannic acid came to have more horrors than the devil himself Saline baths bags, oils ointments a profusion of old treatments were revived or suggested The battle of burns was on and the practitioner has stood and stared and looked up at it pardonably a little bewildered The short treatise of a hundred pages by Mr A B Wallace[7] brings with it an ebullition of cooler reason "Up to the present and generally speaking the employment of one of the tanning agents is undoubtedly the method of choice in the treatment of burns" he says But he makes it clear that he does not like tannic acid for the hands and for what are now called deep or third-degree urns On the face he has had good results with anning and has not been troubled by corneal ulceration He describes in detail the various methods that may be mployed especially saline baths and comments that here are particularly promising hopes for the treatment of third-degree burns with Euglamide—a sulphonamide cod-liver oil glycerin dressing introduced by the Edinburgh school For first aid treatment he would have no ocal substance applied and the patient merely brought o hospital as soon as possible The whole book is packed with practical suggestions He gives charts how o estimate the extent of the surface lesion, details of how o maintain the water balance the amount of serum equired and even the details of serum preparation Particularly valuable are his constant references to the elative amounts required in the treatment of burns of nfants and children His suggestion of taking half-hourly rectal temperatures and blood-pressure records is not always feasible in time of war and frequent recordings of blood pressure are often distressing for the patient with wollen burnt arms His illustrations of how to set out rollers will be of particular value in organising burns units whose importance he urges strongly. Some of the ther drawings showing the cleaning of the patient are ot however very instructive and their space might have erved for greater encouragement of skin-grafting and fuller description of its technique Nor is it essential specially in the light of the E M S memorandum on he treatment of burns[8] in which soap and water are ecommended, to insist on the use of saline only for the cleaning of the burn But he sets out clearly the recent advances of this war—even to the air filter for the drier, since the danger of disseminating dust-borne bacteria has been recognised

BACTERIOLOGICAL DIAGNOSIS OF TUBERCULOSIS

DEMONSTRATION of the causative organism in material from an affected patient is with minor qualifications the most reliable method for the diagnosis of any infection Tuberculosis is no exception but the bacteriological diagnosis of tuberculous infection is far from satisfactory and attempts to demonstrate the organism are often made in too perfunctory a manner. In the case of pulmonary tuberculosis even when a diagnosis of parenchymatous infection is made by other than bacteriological means it may be all-important both for the patient and the community to know if tubercle bacilli are being expectorated The methods available are direct microscopic examination of the sputum before and after concentration culture on suitable media and guineapig inoculation whenever the diagnosis is in doubt all three methods should be used In the direct microscopic examination of sputum there are certain essentials which must never be omitted Among them are the need for examining several daily specimens of the morning spit and in the laboratory scrupulous cleanliness of glass-ware, preparation of the smear from a purulent speck diligent microscopic search and precautions against saprophytic acid-fast bacilli from cold-water taps, corks and the like The value of microscopic examination of the concentrated deposit after treatment of the sputum with antiformin or normal soda is not generally appreciated—for example in one recent series out of 112 specimens microscopically negative on direct examination 33 were positive on culture, and of these the smears of 16 concentrated deposits were microscopically positive so that an immediate report could be given

Where sputum is not available examination of gastric contents or of fæces is recommended, particularly in children who tend to swallow their secretions An alternative and easier, procedure is the use of the laryngeal swab and Nassau[1] has lately shown how the technique can be used culturally for the isolation of tubercle bacilli from apparently sputum-free patients; the results were particularly good in women in those undergoing collapse therapy, and in the diagnosis of early infiltrative lung lesions The swab moistened in water, is passed into the larynx with or without the aid of a mirror and the patient is asked to cough On receipt at the laboratory the swab is placed for 5 minutes in 10% sulphuric acid transferred to 2% sodium hydroxide for 5–8 minutes and then rubbed over the culture medium. In two groups of 166 and 107 patients who were originally sputum-free or had ceased to expectorate 37 9 and 54 2% respectively gave positive cultures from the laryngeal swab

The satisfying results obtained from culturing suspected tuberculous material in screw-cap bottles on the newer media—Löwenstein-Jensen,[2] Petragnani[3] Jameson's[4] medium, and now a bean-egg medium[5]—are gradually becoming more widely known but the best method for concentration of sputum or other contaminated material the amount of inoculum the number of culture tubes to be inoculated, and the optimum gaseous and pH environment are points about which there is as yet no finality. Failures occur inexplicably and in any large series in which the results obtained by smear, culture and guineapig inoculation are compared no one method gives 100% of positives In a recent analysis of a miscellaneous

collection of sputa, urines, pus, pleural and cerebrospinal fluids from tuberculous cases (total positive, 321) Whitehead[6] had 139 specimens positive on culture which were negative microscopically, but he also had 27 positive smears with corresponding negative culture Again, 31 specimens were positive on culture but negative in the guineapig (9 animals died prematurely), while 23 specimens, negative on culture, were positive in the guineapig Obviously there are factors concerned in the recovery of the tubercle bacillus from infected material which still need elucidation

ABSORPTION OF IMPLANTED HORMONE TABLETS

THE administration of hormones by the subcutaneous implantation of compressed tablets[7] may now be said to have passed the experimental stage and to have proved its value, especially when a long, steady dosage is required The technique has received considerable clinical attention and minor difficulties such as preparation and sterilisation have been largely overcome It is also generally agreed that, after the implantation of tablets into a pocket of the subcutaneous tissue and closure with a stitch the skin heals normally and no local disturbance results A tight capsule composed of connective tissue forms around the tablet It varies in vascularity, and is of doubtful influence on the rate of absorption Menopausal or postmenopausal women with symptoms controllable by œstrogens, eunuchs or eunuchoids, and cases of Addison's disease are typical examples of subjects in which the implantation of tablets gives continued therapy, without frequent injections, with substances of small or doubtful activity by mouth In these cases, the longer a single implantation is effective the better for the patient, hence it is necessary to know the level of dosage we can expect a tablet or nest of tablets to give after it has been in situ for some time Relatively few observations of the rate at which absorption continues as the tablet diminishes in size have been made in the human subject, but in one of the most detailed reports, Geist and others[8] conclude that tablets of œstradiol, implanted in women, become so isolated by the progressive formation of a thick capsule of connective tissue that after a period of about 3 months absorption almost ceases They prefer to use loose crystals for clinical implantations, for these produce less encapsulation than tablets On the other hand, Thorn and Firor[9] have studied the absorption rates of tablets of desoxycorticosterone acetate in man, and their results show that the absorption from a tablet left in situ for nearly 250 days continues at much the same rate as that from tablets implanted for shorter periods They comment on the regularity of the rate of absorption, and conclude that a single implantation of tablets of the hormone should supply enough material to last 9–12 months

This problem of the rate of absorption and its maintenance is more easily investigated with animal material Emmens[10] has implanted uniformly compressed disc-shaped tablets, of testosterone, œstradiol and diethylstilbœstrol, and a large series of their mono- or di-esters into male rats The tablets were as uniform in weight and size as could be obtained, and were removed at intervals of up to 85 days, weighed and reimplanted in a fresh site The variation in the rate of absorption from tablet to tablet of the same substance was small, especially for the steroids As found by Thorn and Firor with desoxycorticosterone, the rates of absorption tended not to fall but to remain at about the initial level even when a considerable percentage of the tablet had been absorbed Emmens concludes that a practically constant dose level may be maintained throughout the greater part of the life of such a ta as long as the danger of sudden crumbling is avoided care in manufacture Esterification of the substa reduces the rate of absorption, and it should be ex by choosing a suitable ester and using several tablets implantation, to administer a steady adequate do for very long periods by a single operation A similar investigation was carried out by Forbes,[11] who used cylindrical tablets of uniform compression Forbes excised tablets from his rats at various intervals after implantation, and did not reimplant them Unfortunately, he used tablets of such a shape and weight (6-10 mg) that 90% absorption took only 88 days with the most slowly absorbed substance, progesterone so that the effect of prolonged encapsulation was not observable However, he says that in cases where a tablet is surrounded by a thicker capsule than usual the rate of absorption tends to differ somewhat from the others—it appears from his figures to be most often *greater* than usual These data show conclusively that encapsulation in animals does not prevent absorption which continued at a steady rate in Forbes's experiments until 90% of the tablet was absorbed, except with progesterone, which showed a decrease in the absorption rate as time went on

Fears that the long-implanted tablet loses its usefulness, or even that its output decreases as much as theory might predict, thus seem to be ill founded The results of Geist and his colleagues with œstradiol cannot be ignored, but need confirming before they can be accepted as of general application Since these workers used physiological criteria by which to measure the output of the tablets, it is not impossible that they were working near the threshold of response, and that a slight decrease in absorption was erroneously interpreted as a cessation or near cessation

PLANNING FOR MENTAL HEALTH

IN 1938 the Council of the British Medical Association appointed a committee, under the chairmanship of Dr R G Gordon, to inquire into and report upon the provision for dealing with mental health in this country, with special reference to the psychoneuroses and allied disorders The work of the committee, apart from consideration of the report, was completed before the war broke out, the report[12] has now appeared and give a useful survey of our facilities for mental treatment up to that time, with a model scheme for an organised mental health service The committee emphasise the essential unity of mental and physical illness, they cannot be divorced from each other and in all diseases both the psychic and somatic components must be taken into account They quote Dunbar, Wolfe and co workers who found the psychic factor important for the illness in some 80% of hospital admissions, and on that and other evidence conclude that in any group of sick persons something like 30% will be found to be suffering from conditions in which it is helpful to have psychiatric advice The committee agree that no clear distinction can be made between the psychoneuroses and the psychoses, and that the conditions diagnosed can be ranged in such a way that the actually or potentially psychotic form one end of a scale at the other end of which are those psychoneurotics who are no more liable to develop a psychosis than anyone else The size of the mental health problem is manifest in their frank statement that it is at present impossible to provide treatment for all those demanding or requiring it, and they repeatedly urge the need for more doctors trained in psychological medicine, and for greater attention to psychiatric training in the medical curriculum The inpatient provision for chronic psychotic patients, they think, is reasonably efficient and the provision for intary and temporary patients in some areas is good , they recognise an urgent need for special accommodation for the treatment of those acutely ill patients o have a prospect of recovery These, they wisely d, should be treated in separate units from those vided for chronic patients Moreover they point t that there is at present no special provision for ronic neurotic patients who constitute a serious social oblem Among many valuable recommendations ey suggest that some uniform system of follow-up d assessment of results should be adopted by the rger institutions undertaking treatment Certainly e have much to learn about the value of psychotherapy, d uniform records would in a few years make a large dy of information accessible

FATAL STINGS

SUDDEN deaths after a sting by bee or wasp are rare ut not unheard of The two examples recorded by r Dyke on another page can be supplemented by nother which was reported in the daily press last week n East London A married woman of 43 had kept bees or two years and had often been stung without more han the usual unpleasantness In the middle of July, however, she was stung on the neck and ten minutes later her chest felt tight and she found difficulty in breathing either in or out She looked blue and felt faint, but in half an hour was well again Six weeks later she was attending to her bees, wearing gauntlets and trousers, with a veil over her face, when she was stung four times in quick succession, on the left ankle, on the dorsum of her right foot and twice on her right calf She took little notice for seven or eight minutes, when she again felt tight in the chest, and hurried anxiously indoors to lie down After another two or three minutes she was deeply cyanosed, her chest seemed fixed and she was frothing at the mouth She died about twelve minutes after the stings No treatment was given All the stings looked alike, with a central weal 2 mm across and an outer ring of erythema 8–10 mm across , there was no rash elsewhere At the autopsy Dr Keith Simpson found no pre-existing disease The body was deeply cyanosed and there was slight œdema of the lungs, filling the terminal airways and producing some ballooning The cause of death was ‘ allergic shock due to bee-stings ” The woman had twin daughters, aged 15, and a month ago one of these developed sudden pain in the upper abdomen with generalised itching and widespread urticaria within five minutes of being stung by a bee Her sister has shown no unusual reaction to stings The coroner suggested that both of them should avoid bees in future

These people clearly die from the violent tetanic contraction of the bronchial muscles such as is seen in anaphylactic shock, but why they do so is not so clear Bee venom is a complicated mixture,[1] but the more reliable recent work points to the main toxic fraction being a dialysable protein of low molecular weight Wasp venom is probably much the same, though there s little cross immunity between the two Hypersensitivity seems to be the likely explanation, but this cannot be the whole one, for bee-keepers have noted severe general reactions at one time and not a day or two later Massive dosage may play a part, but deaths have followed single as well as multiple stings Dyke favours Roch’s view that the fatal sting happens to pierce a vein, and Ryle[2] has supported this view in reporting a severe general reaction after a sting which made no mark In the latest case, too, Simpson found a minute puncture n a vein underlying one of the stings in the calf Dyke points out that in all the recorded cases the patient has died within half an hour of the sting, but death is not immediate, and there would be time to give an injection of adrenaline if this was handy The cautious bee-keeper might keep a tube-type syringe containing adrenaline on the mantelpiece

A NEW ANTIMALARIAL DRUG

So far all compounds which have a definite action against malaria of man have also proved effective against malaria of birds, although not always to the same degree The converse, unfortunately does not hold true, so that tests with bird malaria while they afford a convenient and indeed essential, method for the preliminary evaluation of the antimalarial properties of new synthetic compounds, serve principally as a means of selecting those which are worthy of further tests on human parasites, and for eliminating those which have no antimalarial action Testing by means of bird malaria (especially *Plasmodium relictum* in canaries) has been in progress on a large scale in Germany, Great Britain France and Russia for the past 15–20 years and all the new synthetic compounds with proved antimalarial action in human malaria—Plasmochin, Atebrin, Fourneau 710, Plasmocide and so on—have been discovered in this way Work on similar lines has been going on in America and now Hegner and his co-workers[1] report the discovery of another effective compound in the derivative of quinine known as hydroxyethylapocupreine which has been used for several years in the treatment of pneumonia[2] They claim that this drug is much less toxic than quinine (it produced no toxic manifestations in the pneumonia cases), and about equally effective against the parasites of bird malaria They made tests with three species of bird malaria—*P lophuræ* in young Pekin ducks, *P relictum* in pigeons, and *P cathemerium* in canaries The new compound showed antimalarial action, more or less similar to that of quinine hydrochloride, against all three parasites No precise figures are given for the maximum tolerated and minimum effective doses with respect to the different parasites, but it appears from the experiments on *P cathemerium* that the therapeutic index (minimum effective dose . maximum tolerated dose) is about the same as that of quinine, which is 1 4 The lower toxicity of the new drug would be valuable if this increased its therapeutic index, but if the minimum effective dose is correspondingly higher than that of quinine more of it will have to be given to achieve a similar antimalarial effect and there will be little practical advantage unless it is much cheaper than quinine

In birds the new compound proved equally effective when administered by mouth, intravenously, intraperitoneally and intramuscularly , it remains to be seen what its action will be in man

AMORY PRIZE—The first award of this septennial prize has been made by the American Academy of Arts and Sciences to Dr Joseph F McCarthy, professor of urology at the New York Polyclinic, Mr Carl R Moore, Ph.D , professor of zoology in the University of Chicago Dr Hugh H Young professor of urology in the Johns Hopkins University, and a European scientist whose name is temporarily withheld as he lives in a country dominated by Nazi Germany The prize, which is the income from a fund established by the late Francis Amory in 1912, amounts to nearly $16,000 and it will be equally divided between the four scientists It was offered for contributions to the treatment and cure of diseases of the genito urinary system Dr McCarthy has developed instrumental procedures for the diagnosis and treatment by way of the urethra, without external excision, of diseases of the bladder and prostate Dr Moore has investigated the physiology of the male reproductive tract, especially as it is influenced by the hormonal secretions of the male sex gland Dr Young has devised an operation of total prostatectomy by the perineal approach for the relief of obstruction of the bladder caused by cancer of the prostate gland

THE CHANGING FACE OF MEDICINE IN NEW ZEALAND

LAST year New Zealand celebrated the centenary of its separate existence as a colony, later a dominion, of the British Empire From a handful in 1840 its population has grown to somewhere near two million, 95% of whom are of British stock Its temperate climate is milder than that of Britain and its landscape more varied, but it has no great mineral wealth So its economy is based on farming and its farmers grow the same crops and the same animals as are raised by the farmers of this country. It is not surprising, therefore, that in its domestic life and its social and political institutions it is closer to the tradition of this country than is any other part of the empire This similarity of tradition, together with the small scale and relative simplicity of the New Zealand scene, make the social problems of that country peculiarly interesting to the students of social problems in this New Zealand's problems are test-tube versions of ours, and moreover the New Zealand people are enterprising enough to make experiments with the contents of their test-tubes In the 'nineties they attracted the world's political interest by their liberal legislation—the enfranchisement of women, for example, and the Compulsory Arbitration Act In 1935 a Labour government came into power and, taking control at the outset of the country's finances, has embarked on a programme of social legislation that, in conception at least, is bold, broadminded and progressive One of its measures is a Social Security Act, which includes a plan to nationalise the medical profession This has met with intense opposition from the profession, and has not yet been carried into effect

The background and the progress of this experiment deserve study outside New Zealand They are described in a small book, "Medicine and Health in New Zealand,"[1] by Douglas Robb, an Auckland surgeon in his early forties He sees the problem as one part of the major task of modern civilisation which is the adaptation of social institutions to the changed conditions of man's life brought about by applied science Social institutions are slow growers, and their adaptation lags, but it must inevitably come To resist it is as futile as Canute To study it, to influence its speed and form, is the only course open to an intelligent mind Robb describes the public hospitals of New Zealand, financed partly from rates and partly from the government, each controlled by a lay board elected locally in a political atmosphere He allows that they do a great deal of good work, but he finds that they fall short of what they should do—namely, dispense to the people of the country the best advice and treatment that modern scientific medicine can offer, and dispense it as soon as it is available They fall short because there are many of them and they do not work in cooperation Expensive equipment is not concentrated and made available in large centres and there kept up to date, but small hospitals attempt more than they can properly accomplish or maintain

The same is true of personnel Technical specialism is not sufficiently advanced—in one of the largest hospitals, for instance, gynæcology is still part of the field of the general surgeon The country's chest surgery and brain surgery are not in the hands of a few well-trained men, who alone could do them really well The reason for this is that the organisation of hospital staffs (who are still honorary although the hospitals are state-financed) is determined not by the fact that hospital patients need treatment but by the fact that members of the staff need to earn their living in private practice The two needs do not run parallel, and when in addition appointments are liable to be made and unmade capriciously by a politically minded lay board without professional advice, the standard of work done must be less than the best In general practice the same conflict occurs What the practitioner mostly does, and what he becomes most interested in, is what patients can and will pay for, not primarily what patients need He cannot help this attitude, for he must earn his bread He cannot help preferring the removal of one child's inflamed appendix to the patient investigation reasons for another child's wetting the bed It is individual fault that the economic rules under works do not allow him to do the best that medicine do for every patient The fact that he is in co private practice is the chief reason why he cont to preventive medicine, does nothing in the nature research, and does not even succeed in fully devel that aspect of the family doctor's relation to his which might be called pastoral care

By discussion of this theme, with variations, makes it clear that reorganisation of New Zeal hospitals should be attempted along what he "functional" lines The prime considerations are the patients' needs and how the resources of modern medicine may most efficiently be brought to meet them A loca elected hospital board in a small district cannot wei these, more coordination of districts, with a measure of central control, is needed, and that central should include non-political voices, many of medical Staff appointments should be made with those prime considerations in view, and by bodies on which the best disinterested professional opinion is well represented. Posts of the registrar type should be instituted Staff should be no longer honorary, but reasonably paid and pensioned He does not discuss in detail whether they should be full-time or part-time This problem is bound up with that of the future of general practice The Social Security Act of 1938 promised a free maternity and general practitioner service to the whole population, but the government has not yet succeeded in introducing it The B M A in New Zealand had already formulated a scheme based on the insurance principle, and applicable by an income limit to 70–80% of the population The government insisted, however, on universal application, and rejected the B M A scheme It began discussions with the B M A on how a universal scheme might be worked, whether on a purely salaried basis, on a capitation basis, or by paying the doctor so much per attendance on every patient coming to him It succeeded in getting an agreed scheme for a maternity service, which is now operating, on the attendance basis, but on the general practitioner service the discussions reached a deadlock which looks like lasting until the return of medical men from overseas service at the end of the war In February last the government actually brought into force a general practitioner service on a capitation basis (15*s* per patient plus mileage) but the president of the B M A announced the non-cooperation of members and since then only a handful of doctors have signed contracts Last week however the government amended the Social Security Act by changing the doctor's payment from a capitation fee of 15*s* to a consultation fee of 5*s* (6*s* 6*d* a home visit), plus mileage as before

Robb holds that reorganisation of hospitals and specialist services is more urgently needed than that of the general practitioner's conditions of work He favours the idea of the American community hospital which serves all members of its community, and elimin ates the ill-equipped uneconomic small private hospital He discusses the bearing of possible re organisation on medical education He describes the widely varying reactions of New Zealand medical men t reconstructive suggestions The younger ones, who i larger proportion than their seniors have had post graduate experience abroad, find it more difficult than their seniors to establish themselves in practice and earn a livelihood, they see the deficiencies, and itch to remedy them more or less radically The older ones, as a group are strongly conservative From their social origins Robb thinks, from the narrow and technical nature of their "university" education, doctors as a class tend to grow conservative, their detailed and absorbing daily work, their close dependance, when success comes in practice, on local conditions and relationships, make them more conservative as they grow older, more satis fied with the status quo There is considerable "feeling" between these age-groups, which is unfortunate unworthy, and hinders progress without directing it Robb concludes with an appeal for an informed an competent survey of the situation of medicine and health in New Zealand, adding gently that "amongst th surveyors there should be at least some whose in the future rather than in the past." From the ev an acceptable plan should emerge. for the total blem in New Zealand is a bagatelle compared with in Britain."

---

ch a survey would certainly be of great interest to various bodies in this country in whom the yeast of lanning" is at work. and they would welcome still re warmly a serious attempt. made by the government d the profession in New Zealand. to realise a coöperative eme of medical services in which patients would be ter served than ever. and doctors freed from the straints of economic competition. yet not fettered by se of bureaucratic organisation.

MEDICINE AND THE LAW

A Masseur's Negligence

DAMAGES for negligence were awarded lately in the ymouth county court against George Carter who scribing himself as a masseur and medical electrician. d undertaken to treat Miss Winifred Snell. a woman of 2, for disseminated sclerosis. The patient's mother said at the defendant had been told of Miss Snell's condition nd had agreed to carry out four treatments a week at s. 6d. per treatment. He had told her that he was treating somebody else for the same complaint. Two treatments were given on successive days; the patient's back was massaged with oil and ray lamps were used. Soon after the second treatment. the skin began to come off the back which was severely burned. The burns became gangrenous and. after suffering great pain. the patient died of toxæmia. Dr. S. Noy Scott gave evidence that ray treatment was inadvisable and useless: the disease made the skin insensitive to heat. Anyone with medical knowledge. he said. would realise the danger of ray treatment in such a case. Carter. conducting his own defence. denied that he had been told the nature of the patient's illness: he attributed the wounds to chafing set up by incontinence. Answering the judge he stated that he had no certificate of competence. but he had long experience. having practised for twelve years. He had spent three years in the Victor Institute in Australia. an institution conducted by an American: he left it when the American died. He considered that he knew when ray treatment would be dangerous; he had books which told him when it should or should not be given. Before becoming a masseur. he had been a merchant seaman. Asked by the court if it was his practice to take a patient without proper knowledge of the medical attendant's diagnosis. he replied that patients were usually recommended to him by doctors.

His Honour Judge Scobell Armstrong said he must find Carter negligent in law: he awarded Mrs. Snell £59 1s 6d damages. He went on to offer the court's "full sympathy" to the defendant. regarding him as a person entirely competent to perform work under a doctor's recommendations in all normal cases: unfortunately this had been "a very unusual case."

If comment can be added without disrespect to a careful and courteous tribunal. the decision and its rider exhibit the national compromise between two views of unqualified practice. One view resents any control of such practice, because unsupervised masseurs like the defendant may possess or may at any moment discover some therapeutic secret overlooked by orthodox medicine and because there is much more scientific truth in the world about us than is dreamt of in the registered medical practitioner's philosophy. The other view is that it is unfair to the public to leave electrical or radiological treatment so utterly uncontrolled that an unqualified man can cause fatal burns to a patient suffering from disseminated sclerosis. On this view the sympathy is even more needed by the public than by the unqualified man. Accordingly many progressive municipalities and at least one county council have successfully promoted legislation authorising them to license and supervise establishments for massage and special treatment such as electric or radiant heat therapy. Unlicensed practice is prohibited and licences can be refused where applicants do not possess such technical qualifications as may be reasonably necessary. There is no need to wrangle over complaints of professional monopoly; the defendant at Plymouth had all the freedom he could desire. If the public interest alone be regarded, would it, or would it not, be "reasonably necessary" that an unqualified practitioner who takes money for administering ray treatment should possess and apply the knowledge that there may be "very unusual cases" where his ray lamps will do more harm than good?

Volition in Matrimonial Desertion

Desertion. for the purposes of our divorce law. must be a deliberate and intended act. A patient in a mental hospital if incapable of "the quality of volition required to produce legal consequences" cannot be guilty of desertion. This point was fully examined two years ago in *Williams v. Williams*. Each case. however. turns upon its own facts: the mere suggestion of mental ill health will not establish incapacity of intention. Recently in *Monckton v. Monckton* the facts were as follows. In 1937 the wife ordered her husband out of her house in which they lived and had told him to remove all his possessions. Two years later she went into a mental hospital as a temporary patient. After a year as temporary patient. she was re-graded as a voluntary patient on Dec. 20. 1939; she was discharged on Jan. 22 1940. While in hospital she wrote affectionate letters to her husband which held out some prospect of reconciliation. But on Jan. 9. 1940 when he went to France with his regiment. there was a quarrel and she declared that she never wanted to see him again. She refused to change this attitude when on his return from France. he appealed to her to join him. He then petitioned for divorce on the ground of her desertion.

Under the Herbert Act he had to show that she had deserted him without cause for at least three years immediately preceding his petition. Had her mental condition been such that she could not decide for herself whether she should or should not enter the hospital? If so the husband would be unable to prove her intention to desert and her persistence in that intention for the necessary three-year period. Mr. Justice Henn Collins said that, on the facts before him the court could not infer any such degree of insanity or lack of the "quality of volition." He granted a decree *nisi*.

Alleged Delay in Hospital Treatment

Hospital authorities are probably well aware that a few words hurriedly spoken at the admission of a patient can create the impression of some defect of care and sympathy. At a recent Manchester inquest upon a little girl who died three hours after being taken to the Crumpsall Hospital a constable and a police ambulance driver gave evidence of statements by the casualty ward sister that the child should not have been brought there but should have been taken to another hospital specially prepared to receive children. It was also alleged that an injection of morphia was not given till half an hour after the child suffering from severe burns had been admitted. and that it was a quarter of an hour before the policeman's cape in which she was wrapped was removed and warm blankets were applied. The ward sister denied saying that children were not admitted at the Crumpsall Hospital; there was no delay in giving the injection: the child was placed in warm blankets and the doctor sent for within five minutes of arrival. She denied that when the police officers asked her to give first-aid she replied that it was not a first-aid post. There was dispute about the entries and times recorded in the hospital books. Two medical officers at the hospital testified that the child received the best and quickest possible attention from the staff and that the hospital regulations had been faithfully carried out.

The coroner said it appeared to be a rule of the hospital that normally no child under 16 should be admitted as an inpatient, but these instructions included the order that, irrespective of age any patient should be admitted if his or her condition warranted it and that the doctor who saw the patient should judge his or her condition. He was himself satisfied that the dominant idea in the ward sister's mind was that the child being under 16, should be taken to the Booth Hall Hospital. In the result the child suffered some unnecessary pain and suffering. Life might not have been saved or even prolonged but proper treatment would have made her remaining hours a little more comfortable. He hoped that in future the administrators of the hospital and the medical superintendent himself would make sure that all orders issued to the staff were thoroughly understood and obeyed He recorded a verdict of death by misadventure He had found, he said several contradictions in the evidence and, as an old member of the bar with many years' experience, claimed to judge from the demeanour of a witness as well as from the testimony given He had by the way, asked the two medical officers who gave evidence to leave the court while the ward sister was in the witness-box This forensic precaution against possible conspiracy and perjury is not universally taken in the case of professional witnesses

AN ACCEPTABLE STATE MEDICAL SERVICE

AN open meeting of North London general practitioners from the City of London and the boroughs of Hackney, Finsbury, Stoke Newington, Shoreditch and Bethnal Green, was called by the Practitioners Coordinating Committee on Sept 2 at Islington, to discuss a state medical service

Dr M F MOLONEY, who was in the chair, mentioned the dissatisfaction which many doctors felt at the lack of representatives of general practitioners on the B M A Medical Planning Commission In medicine today he said, the doctor often worked alone in his own surgery with inadequate equipment for the diagnosis, investigation and treatment of disease The patient got the best treatment his doctor could give him with the means at his disposal, but not the best that could be had Nor was the doctor's position becoming any easier National Health Insurance had been extended to include those with incomes of £420 Public-health clinics though progressive and valuable, were encroaching on the territory of the general practitioner He urged that general practitioners should see that those representing their interests on the planning commission or other bodies really did advocate their policy, and that they were not mere yes-men Those doctors who were not members of organisations should talk to their friends and colleagues until an informed body of thought was available

Dr B HYNES thought that, to ensure that all general practitioners were properly utilised in a state scheme, three plans were needed an urban, a suburban and a rural plan Discussing the needs of an urban area he suggested that a large borough like Islington would be divided into centres serving 10,000–11,000 people There would be a unit or clinic housed in a two-story building, placed where it would be easily accessible to the residents of the neighbourhood The ground floor would contain the dispensary, surgery, nurses' side-room, waiting-hall and five small consulting-rooms with examination-rooms opening from each Clerical work, apart from medical note-taking, would be done by a secretary in the office by the front door Upstairs there would be sleeping accommodation for two doctors living quarters for the nurse, two small observation wards, a large sitting-room (also to be used for medical meetings and conferences) a pathology laboratory for simple tests and investigations, and a small X-ray plant by which the presence of fractures could be decided without loss of time The personnel would consist of 10 doctors, working on a rota, 4 in daily session for surgeries and visiting, 2 on night duty (one to take calls and the other to attend emergency admissions) and 2 off duty There would be a day and a night nurse, possibly with a relief a combined laboratory and X-ray attendant, a clerk and a porter Salaries should be appropriate to the posts, and the doctors should get three or four weeks holiday on pay and additional time off to attend periodical refresher courses There would be provision for sick pay, and for a pension on retirement

Dr W W FOX remarked that he had not been in favour of a state medical service in the first place, because he felt the practitioner could do better for himself than the state would do for him, but he had come to the conclusion that unless general practitioners made their wishes known a state service would be introduced based on an extension of the principle of the capitation fee Doctors had asked for an increase of the capitation fee in vain Lately the £420 income group from whom general practitioners until now had derived an appreciable part of their income had been brought under national health insurance, with an increase of a mere 9*d* on the capitation fee, whereas the dependants of persons—who really needed to be brought int scheme—were still left outside it The numl patients whom one doctor could attend were limit Russia they had begun by assigning 2500 to each d but had now decided that 1000 was a sufficient n for one man to attend In the British Medical tion the profession had the machinery by which it make its wishes known but those who dissented B M A policy were not sufficiently organised at p to give a unified opinion, and it was for this reason the Practitioners Coordinating Committee had formed

Dr P INWALD, discussing the loss of free choice doctor which any rota system must entail, said t patients attending hospital were willing to acc treatment from doctors whom they had not chosen pointed out that the prospects of the general practitio were not at present secure if he kept his health, and his investments were sound he might have an income £4–£6 a week at 65 If he fell sick or died he generally left his dependants unprovided General practitioners formed 55% of the profession, and should be represented in this proportion on any body planning for the futur of medicine

A RESOLUTION

In the discussion which followed most speakers accepted the view that a state medical service was likely and agreed that a united body of opinion from general practitioners would help to safeguard their interests One speaker, in the municipal service saw in a state medical service a welcome end to the rivalry between the public-health clinics and the general practitioners Another warned the meeting that salaries under a state service were likely to fall far short of those attainable in practice, but was reminded by Dr Fox that a net salary was a different thing from a gross income with high overhead expenses The following resolution was then presented by Dr D LENIHAN and seconded by Dr G W MACKAY

> In order to improve the medical services to the public and to provide the fullest facilities of modern medicine, preventive and curative, and in the light of recent development recognising the probability of some form of state medical service, this meeting of medical men is prepared to accept such a service provided it includes the following aims adequate consideration of the just requirements of the general practitioners of the country, adequate compensation for existing practices, salaries based on years of service and experience rather than capitation fees, pensions on retirement, limited daily hours of attendance and time off duty each week, annual leave on pay, periodical refresher courses on pay, opportunities for obtaining specialised experience and research, access to hospitals, clinics established as centres for general practice, fair representation of general practitioners on any planning board for the institution of a state medical service, and in its subsequent administration

A vote was taken immediately afterwards and the resolution was accepted by a large proportion of those present Representatives were then coopted from the members of the various boroughs present, to help in furthering the work of the committee

SICK BAY FOR SHELTERERS

THE first central shelter sick bay in the London re for those using public air-raid shelters has been ope by the Corporation of London in the basement of t Cheapside It is intended for the use of those shelt dwellers who have minor illnesses of the kind which would ordinarily keep them in bed at home for a day o two, but which, during severe raids, would not restr them from going to the shelter Children suspected of incubating an infectious disease can also be kept in bed there, under supervision until they make their intentio clear Thus the sick bay should prove a valuable bulwark next winter against the spread of upper respiratory infections and the exanthemata A doctor is attached to the post, on call, and three or four Red Cross nurses are in attendance

The white tiled basement two floors below ground level and protected by many stories of steel and co e, was an ideal site for the new venture No con- ction was needed apart from some plain wooden titions painted white by which the space was divided into two wards—one for men and one for women— d a consulting-room Water is laid on, and there are emical closets on the same floor, while on the floor above ere are water-closets and wash-basins The wards are ored with brown linoleum , each contains six beds but ere is room to put up twelve more beds if they are eded At present they are comfortably spaced out ith unusual lockers in white wood standing between em These lockers can be swung round so that the wer part slides under the bed and the upper part can e opened out as a bed-table To the newcomer the bed- overs come as a delightful shock to the eye they are atchwork quilts made by hand in the gayest of colours y the Canadian Red Cross for the W V S Nothing ould give a better touch of brilliance and homeliness to he wards The surgical equipment provided, with much lse, by Messrs Evans Sons Lescher and Webb is simple out plentiful, including Spencer Wells forceps, dressing scissors, ear speculums irrigators and such usual weapons of the doctor's surgery It is not intended, of course, that any major surgical procedures will be undertaken in the sick bay The firm have also supplied a useful assortment of drugs and stock remedies, and have met all the everyday needs of nursing in shaving tackle, bedpans air-cushions and tooth mugs , there is even an electric kettle The beds and mattresses were provided by the Ministry of Health and so were the cupboards which are of the type usually supplied to shelters Pyjamas, dressing-gowns, bedlinen and blankets have come from the W V S The consulting-room is spacious, with a desk a comfortable divan, and a good light A Turkey carpet, given by one of the medical staff, robs it of that bleakness which is apt, in hospitals, to have a discouraging effect on patients

The sick bay has only been open since the last week of August, and so far no patients have been admitted, but the patchwork quilts may soon find themselves on active service

CANADIAN MEDICAL TRAINING *

MEDICAL education in Canada is primarily the responsibility of the university rather than the hospital Preclinical subjects, biochemistry physiology and anatomy are taught in the university, which is closely associated with one or more general hospitals as well as with the civic fever hospitals, children's hospitals, and provincial hospital services for tuberculosis and mental disease The requirements for entrance to the various universities differ somewhat, but having enrolled at university the student spends one or two years studying physics, chemistry, biology and the other premedical subjects, or he may be required to proceed to a B A degree The medical course proper requires four, five or six years, the sessions of university in peace-time starting about the third week in September and ending in the third week in May There is a ten-day holiday at Christmas and a *long* week-end at Easter Since the outbreak of war some schools have lengthened the academic year by two months and made changes in the time-table thus shortening the course by a year

There is some variation in the plan of the curriculum from one medical school to another but in all great emphasis is laid on anatomy, physiology and biochemistry during the early years The teaching of anatomy, generally speaking, follows the British example of emphasising detailed thoroughness and completeness Courses in physiology differ but little from those in this country, although perhaps greater opportunity exists for Canadian classes, divided into small groups, to carry out a series of experiments on animals Research fellowships or appointments are available for undergraduates wishing to spend an extra year working at anatomy, physiology or biochemistry at the universities, particularly at the larger ones Pathology is a long and heavy course in all schools, and an outstanding effort is made to correlate all aspects of the course—the museum morbid anatomy and microscopical study—with the problems of clinical medicine In all clinical subjects teaching at the bedside occupies much of the student's time Closely supervised activity as a clinical clerk is a feature of the student's final year at university in most of the schools

Examinations are held at the end of each year and the degree of M D. is conferred upon successful completion of the final year Following qualification the almost universal practice is to spend a year as a house-surgeon while at least two schools require one year of internship in an approved hospital before granting a degree Excellent opportunities for postgraduate training exist in the hospitals associated with the universities in teaching In most hospitals, junior residents are appointed for a year during which they work on four or more different services It is possible to progress through a series of resident appointments in the larger general hospitals to the posts of R S O , R M O , resident anæsthetist or resident in obstetrics and gynæcology Fellowships and internships in pathology are filled yearly

The Royal College of Physicians and Surgeons of Canada conducts primary examinations which the undergraduate is encouraged to prepare for and to try after the second year of his medical course The final examinations, in medicine or surgery are commonly undertaken, as in England, after several years' training in hospital The universities of Alberta Dalhousie Manitoba, McGill, Queen's Toronto and Western Ontario are all English-speaking universities In the Universite de Montreal and Laval Universite, French is spoken, and teaching has been generally influenced by the French School of medicine

---

In England Now

A Running Commentary by Peripatetic Correspondents

HOW eloquent and incisive are the orations that one makes in the bathroom, how halting and commonplace the speech of which one is delivered in the council chamber The other day I attended a meeting called by the local medical war committee which was addressed by E M S officials, R A M C officers and consulting physicians The audience, composed of consultants, public-health officials and battalion medical officers, took its medicine in glum silence broken only by a little tepid applause The hospital officer instructed the hospital staffs to *fill* in the forms promptly and with due attention , the R A M C explained to the consultants the inner meaning of the Army's funny little ways , the consulting physicians and a professor of medicine told the regimental medical officers that they must exercise more judiciously their diagnostic powers The outpatient clinics of the hospitals are apparently crowded with soldiers referred by the R M O 's—soldiers with coughs with a request that they should be investigated for pulmonary tuberculosis, soldiers with nervous dyspepsia for gastric investigation, soldiers with tachycardia requiring electrocardiographic examination These investigations were not only unnecessary it was said, but they were doing much harm to the soldiers "Come to your conclusions," exhorted the professor eloquently, "and come to your conclusions quickly " The medical officers in the face of the higher stars of their constellation, were silent Next morning while shaving and looking my audience steadily in the eyes, I spoke in their defence

"It is generally admitted " I began, "that the regimental medical officers of today show a distressing inclination towards second opinions and ancillary investigations No useful purpose will be secured in suggesting that they should change their habits of mind and practice The good doctors among them will continue patiently to separate the wheat from the chaff , the less good will by prodigious exertions reduce the number of the cases they send to hospital soldiers with ulcers will be kept in the *unit until final* breakdown the gastric neuroses will continue to be sent to hospital for investigation You must remember," I went on applying more soap, "that these Army doctors were the family doctors of yesterday and the medical students of the day before Some of them may have been Professor X s students Can it have been that their medical education was faulty ? Is it possible that they were taught to regard medicine in the professorial units as an applied science and not as a practical art ? Certainly they were taught that the proper investigation of a chronic cough made necessary a radiogram and a sputum investigation, that no chronic dyspepsia could be correctly assessed without chemical and radiological evidence, that cardiac neurosis was established as a diagnosis when electrocardiograms were negative In short, that neurosis was a negative diagnosis and not to be positively established Which of us was told by the professors that it was better to miss one case of active tuberculosis or cancer than to confirm five neurotics in their neurosis? When did a professor of medicine come to his conclusions quickly? These R M O 's too, were family doctors yesterday *Today they are told by consulting* physicians that they send their patients too readily to hospital for investigation This is apparently true today and it was equally true yesterday, and yet no-one has heard a consulting physician tell his family-doctor clients that it would be better for their patients if they did not refer them for a second opinion and that some patients are made worse and not better by investigation The experienced family doctor knows this, the consulting physician knows it too, but it would require a supernatural disinterestedness in him to preach the good news Moreover most family doctors serve in the national health insurance system which denies them the opportunity to investigate their patients at all deeply, so that reference to hospital with consequent loss of clinical experience or treatment of his patient without diagnostic certitude is the panel doctor's daily dilemma To learn in what circumstances radiology and pathology may safely be discarded in diagnosis requires a clinical experience which can only be acquired by daily contact with them The professors seem to have made a genuine discovery which will have incalculable effects on medical education We may again breed a race of family doctors for whom medicine is a practical art, we may one day give the family doctor a medical service in which ample diagnostic facilities are available for him and his patients "

* This contribution to 'Grand Tour ' reached us too late to appear in the Students' Guide (*Lancet* Aug 31 p 260)

It seemed to me, as I looked in the mirror, that no words of mine had ever had such a friendly and intelligent reception

* * *

We were due to arrive at Crewe station in about half an hour and I noticed with foreboding that little Hector had finished his copy of *Rainbow* He laid the paper on the seat beside him and looked expectantly at me, obviously inviting further suggestions for defeating boredom I had noticed, however, that a Polish airman sitting on the opposite side of the compartment had been craning his neck trying to read the outside page of the comic paper I offered it to him, not without misgivings for I wondered whether he would feel embarrassed To my surprise he not only accepted the paper with sincere but slightly incoherent expressions of gratitude, but promptly settled down to read the simple sentences in which the exploits of the Bruin boys are described Very soon Hector was by his side supplying the low-down on such famous characters as Tiger Tim, Joey the parrot, Georgie Giraffe et alii The Pole concentrated on the narrative with grim earnestness, and would not allow a page to be turned until he had read every word When we prepared to leave the train he folded the *Rainbow* carefully and with a courteous bow of his head handed the paper back to my son Apparently it is not only the British who take their pleasures sadly

* * *

Present happenings in Iran bring back memories of the arrival in Tehran of our small party in September, 1915 It had left home three weeks before for Bergen and had come via Oslo Stockholm Haparanda (at the top end of the Gulf of Bothnia where a frozen river was crossed on foot into Finland), Petrograd and Moscow to Baku, thence by Caspian steamer to the Persian coast and so to the capital, at 3600 feet, by carriage with frequent changes of horses This meant 225 miles in three days and nights and crossing the Elburz chain at 7000 feet Our first sleep was rudely broken Was there anything that would destroy ciphers without smoke? Better not unpack The enemy legations were arming Austrian prisoners escaped from Trans-Caspia in the city, and the Swedish officer instructors were joining them with their native gendarmerie Ahmed Shah was wavering under heavy pressure Later there came a day when feeling sure of him German and Turk, and gendarmes, complete with hangers-on, moved to the shrine town six miles south on the road to which they hoped would once again become the c and waited Cabs disappeared from the streets as food from the shrine His Majesty's travelling was ready One final, day-long interview with our and the Russian ministers and the horses were taken Only the hangers-on and the cabs returned, hungry empty That was not the end of the Allies' troubles Iran remained neutral and the danger in the Middle was scotched, largely by resolute diplomacy, just as this week by *other means* The nightmare of a journey receded We unpacked !

Under Rezah Shah Iran has changed materially many ways since those days All credit to him ! two surprising departures from established policy reported There are only two things that really matter on the great upland plateau, water and bread Since no rain falls from May to October men fight and sometimes kill to maintain their immemorial irrigation right And bread? It was common in this vast area with the harvest dependent on the mountain snows, few roads and only animal transport for there to be famine in one province and plenty in another A good government was one that kept bread cheap and abundant, nothing else mattered But now we read of large scale selling of wheat to the Nazis by the government itself and hunger if not famine Famine in Iran means typhus and relapsing fever as well The second surprise is to find the Nazis in key positions, for these used to be given only to nationals of the smaller powers, thus there were Belgians in the posts and customs, Swedes in the gendarmerie and police, and so on True there were Frenchmen at the medical school, and in the Pasteur Institute and similar posts, but the interests of France were held to be purely cultural, and the Germans had the government hospital up to the last war when it returned to the Persians after two of our own countrymen had completely reorganised it To what a sorry mess this change of policy has led ! However, all's well that ends well the fighting has stopped at Kermanshah and we can hope that at Hamadan, the next city on the road to the interior, old Avicenna will continue to rest undisturbed by high explosives Sheikh Abu Ali ibn' Sina to give him his full name, was a Persian of the eleventh century who wrote their first great system of medicine, the " Qanun," it was translated into Hebrew and Latin and was still read in the seventeenth century at Montpellier so they say Physicians had many interests in those days and Avicenna was a minister of state and a poet as well, a judge of wine and other delights His tomb is still well preserved, and some twenty years ago British initiative led to the restoring of the domed building over it and of the garden in which it stands So much that is pleasant and lovely in life has come from Iran that one recoils sharply from the thought of her intelligent hospitable people being plunged into modern war

* * *

" Any Questions " in the Forces' programme at 5 1 on Sundays is an excellent turn After a bit one seems to know intimately the various members of the Brains Trust and can often predict the tenor of their replies, the scientific, basal approach of Professor Huxley, the god-like survey of Professor Joad, the not very penetrating but always cheery answers of Commander Campbell, which, I am sure, reflect years of tactful presiding at the Captain's table on liners Last Sunday the Trust seemed to be unanimous in advocating the same elementary education for all the children in the country and secondary education only for those who show promise With the justice of this I am in full agreement Quite a number of public schools really belong to the poor Harrow for instance was founded for thirty or forty poor scholars, but in fairly modern times the poor scholars have been legally robbed of their inheritance and pushed down the Hill But I am doubtful about this proposal on other grounds The cleverest man I know—cleverest in that he gets quickest to the kernel of a subject and expresses it pithily—is a gardener, the most instantaneous and devastating at repartee is an Irish-Cockney ex-paperboy the best informed works in an ink factory Presumably, if equal opportunity comes to all, the so of lads that these people were will become civil servants s and professional men and instead of getting the ion cleaved by monetary differences it will be by ellectual ones a deeper schism still At first glance it ms to me to be like robbing the soil of humus in order produce a bumper crop or two In any case it leaves character side out entirely Another point "showg promise" will probably mean aptitude in examinans, in memory, in writing answers in speaking in ord-proficiency Both Leonardo and John Hunter, to ither of whom words came easily even in adult life ould have failed here. By the exam method not only ould one miss the talented picture-thinker who develops late and is dreamily lazy (Why the devil should I orry about your wretched grammar when I can sit ack and watch glorious pictures ?), but one would get hose precocious caterpillars the early word-thinkers ith their excellent memories and no vision who as erfect insects have been responsible for so much of the ness the world's in today Perhaps the educationists ould devise an exam which would pick out these imaginative children "Come Jack (or Jill), tell us a story " I often think we should do the same thing in our professional exams, which at present are almost entirely memory tests Questions like this "Invent and describe (*a*) a new vitamin (*b*) a new venereal disease, (*c*) a brand-new site for the kidneys, showing what anatomical adaptations would be necessary The whole subject needs rumination

---

Public Health

From the Annual Reports

SOUTHERN RHODESIA

Dr Martin's report for 1939, though delayed, is not curtailed The estimated population in mid-1939 was 60,720 Europeans, 5840 coloured and Asiatics and 1,436,560 natives Southern Rhodesia is not in the Commonwealth of the South African Union (though some politicians of the latter think that it should be) but is an English-speaking colony comparable in many respects with New Zealand The statistics for the Europeans are not far different from those of a large English county except for malaria which in 1939 caused 10% of all deaths The standardised death-rate was 10 3, an increase of 0 6 on 1938 ; the birth-rate 23 6, and the infantile mortality 45 The maternal death-rate was 2 1 against 2 in 1938, before which year it had been high, in the neighbourhood of 6 Of 1433 live births, 1029 or 71 8% took place in institutions

During the year 1160 lepers were under treatment at the four institutions in the colony The death-rate of natives employed in the mines sank from 11 9 in 1938 to 9 8 in 1939, the fall being due entirely to diminished mortality from pneumonia This in its turn was partly due to diminished incidence (1841 cases against 2215) and partly to a drop in the fatality from 20 4 to 13 2, attributed to the use of M & B 693 There was also a lowered incidence of scurvy, but still there were 209 cases with 2 deaths "Since every case of scurvy detected represents a condition of subclinical scurvy amongst practically all the natives in the area where the case was found it is obvious that methods of feeding employees still fall far short of satisfactory " A survey of children in the age-group 12 plus revealed infection with urinary bilharzia (*B hæmatobium*) in 6%, and with the intestinal form (*B mansoni*) in 4%

LEEDS

Dr Johnstone Jervis says "There was almost an entire absence of epidemic disease , indeed at no time in the city's history has there been less disease of an infectious character than during the eighteen months that have elapsed since hostilities commenced ' Epidemic diseases ebbed to a low level never previously recorded in all parts of the world in 1938 and this satisfactory state of affairs has continued until the present day The war has so far had no material influence on infectious diseases In Leeds scarlet fever in 1939 gave 960 notified cases with 2 deaths and measles 2274 cases also with 2 deaths As scarlet fever has been notifiable since 1889 and most cases are treated in isolation hospitals the fatalities of the disease are known with fair accuracy We know very little of the fatality of measles, but it has certainly fallen rapidly in recent years The Leeds 1939 rates of 2 deaths per 1000 from scarlet fever and 1 per 1000 from measles are about average for the present time Of 54 300 children found naturally immune or immunised against diphtheria in the past twelve years only 320 developed clinical diphtheria and all recovered In the three years 1936–38 of 158 children protected by measles serum 23 developed jaundice from four weeks to four months after injection all recovered At the time there was an epidemic of infective jaundice in the city, 309 cases being known The incidence of jaundice was therefore far greater in children who had received measles serum than in the general population The jaundice which follows injection of measles serum is not a serious matter clinically but is of great interest, for measles serum is of human origin whereas other sera, except that used for poliomyelitis are of animal origin and do not produce jaundice It is almost certain that the common form of infectious jaundice—formerly called catarrhal jaundice—is a virus disease and it is quite probable that many people are carriers of this virus

SWINDON

Dr Dunstan Brewer in his valedictory report for 1939 draws attention to several ways in which we failed to achieve what we might have done in the inter-war period The chief of these was the failure of hospital coördination and the failure to give children the benefits of physiological research in estimating and developing their endowments Our examination of children is designed to find out what is wrong with them, says Dr Brewer, "and our efficiency is gauged by the extent to which we meddle with their structure If we changed to discovering what was right in our children and give our energy to the direction of functions we should find that we can rear citizens to a degree of health happiness and efficiency which my generation never realised '

From the School Reports

DERBYSHIRE

In spite of coming from what is mainly a reception area Dr W. M Ash s school report shows that in 1940 there were fewer cases of uncleanliness discovered than in 1939, the actual numbers for the two years being 4782 and 5365 There were 12 816 more inspections and reinspections in 1940 than in the previous year, so the lower incidence is not due to diminished search On the other hand scabies (223 cases) was three times as common as in 1939 The number of official evacuees received by Derbyshire in 1940 was 12,115 nearly half of whom came from Southend-on-Sea The nutrition of the received children was distinctly good—slightly better than that of the natives

Infectious Disease in England and Wales

WEEK ENDED AUGUST 30

Notifications —The following cases of infectious disease were notified during the week smallpox 0 scarlet fever 958 , whooping-cough 3173 diphtheria 805 paratyphoid 197 typhoid 68 , measles (excluding rubella) 1112 pneumonia (primary or influenzal) 363 puerperal pyrexia, 136 cerebrospinal fever 99 poliomyelitis, 23 , polio-encephalitis, 5 , encephalitis lethargica 3 , dysentery, 82 ophthalmia neonatorum 87 No case of cholera, plague or typhus fever was notified during the week.

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Aug 27 was 1270 including scarlet fever 115 diphtheria 222 measles 45 whooping-cough 576 , enteritis 22 chicken pox 38 erysipelas 28 mumps 7 poliomyelitis 2 dysentery 21 cerebrospinal fever 16 puerperal sepsis 15 enteric fevers, 16 german measles 1 , polio-encephalitis 2 other diseases (non infectious) 71 not yet diagnosed 73

Deaths —In 126 great towns there were no deaths from measles 2 (0) from enteric fever 1 (0) from scarlet fever 11 (2) from whooping-cough 24 (0) from diphtheria 35 (1) from diarrhœa and enteritis under 2 years and 6 (0) from influenza The figures in parentheses are those for London itself

Derby and Newcastle-under-Lyme each reported 1 death from enteric fever. Liverpool and Stockport each had 3 fatal cases of diphtheria

The number of stillbirths notified during the week was 190 (corresponding to a rate of 38 per thousand total births), including 5 in London taught that the proper investigation of a chronic cough made necessary a radiogram and a sputum investigation that no chronic dyspepsia could be correctly assessed without chemical and radiological evidence, that cardiac neurosis was established as a diagnosis when electrocardiograms were negative In short that neurosis was a negative diagnosis and not to be positively established Which of us was told by the professors that it was better to miss one case of active tuberculosis or cancer than to confirm five neurotics in their neurosis? When did a professor of medicine come to his conclusions quickly? These R M O 's too, were family doctors yesterday Today they are told by consulting physicians that they send their patients too readily to hospital for investigation This is apparently true today and it was equally true yesterday, and yet no-one has heard a consulting physician tell his family-doctor clients that it would be better for their patients if they did not refer them for a second opinion and that some patients are made worse and not better by investigation The experienced family doctor knows this, the consulting physician knows it too, but it would require a supernatural disinterestedness in him to preach the good news Moreover most family doctors serve in the national health insurance system which denies them the opportunity to investigate their patients at all deeply, so that reference to hospital with consequent loss of clinical experience or treatment of his patient without diagnostic certitude is the panel doctor's daily dilemma To learn in what circumstances radiology and pathology may safely be discarded in diagnosis requires a clinical experience which can only be acquired by daily contact with them The professors seem to have made a genuine discovery which will have incalculable effects on medical education We may again breed a race of family doctors for whom medicine is a practical art, we may one day give the family doctor a medical service in which ample diagnostic facilities are available for him and his patients "

It seemed to me, as I looked in the mirror, that no words of mine had ever had such a friendly and intelligent reception

* * *

We were due to arrive at Crewe station in about half an hour and I noticed with foreboding that little Hector had finished his copy of *Rainbow* He laid the paper on the seat beside him and looked expectantly at me, obviously inviting further suggestions for defeating boredom I had noticed, however, that a Polish airman sitting on the opposite side of the compartment had been craning his neck trying to read the outside page of the comic paper I offered it to him, not without misgivings for I wondered whether he would feel embarrassed To my surprise, he not only accepted the paper with sincere but slightly incoherent expressions of gratitude, but promptly settled down to read the simple sentences in which the exploits of the Bruin boys are described Very soon Hector was by his side supplying the low-down on such famous characters as Tiger Tim, Joey the parrot, Georgie Giraffe et alii The Pole concentrated on the narrative with grim earnestness, and would not allow a page to be turned until he had read every word When we prepared to leave the train he folded the *Rainbow* carefully and with a courteous bow of his head handed the paper back to my son Apparently it is not only the British who take their pleasures sadly

* * *

Present happenings in Iran bring back memories of the arrival in Tehran of our small party in September, 1915 It had left home three weeks before for Bergen and had come via Oslo, Stockholm Haparanda (at the top end of the Gulf of Bothnia where a frozen river was crossed on foot into Finland), Petrograd and Moscow to Baku, thence by Caspian steamer to the Persian coast and so to the capital, at 3600 feet, by carriage with frequent changes of horses This meant 225 miles in three days and nights, and crossing the Elburz chain at 7000 feet Our first sleep was rudely broken Was there anything that would destroy ciphers without smoke? Better not unpack The enemy legations were arming Austrian prisoners escaped from Trans-Caspia in the city, and the Swedish officer instructors were joining them with their native gendarmerie Ahmed Shah was wavering under heavy pressure Later there came a day
when feeling sure of him, German and Turk, A
and gendarmes, complete with hangers on, move

Mr S S Zilva, D Sc has continued his work on the itamin-C content of fruits and vegetables With Mr T B Crane, he has shown that the amount of the vitamin n tomatoes does not depend to any great extent on the ariety but that tomatoes grown in the open contain much more vitamin C than those grown under glass

BIOCHEMISTRY

Mr W T D Morgan D Sc, continuing his researches on the antigenic complex of the Shiga dysentery bacillus, has by different methods isolated the specific polysaccharide of the organism in undegraded form This substance is not by itself capable of stimulating the formation of antibody but in combination with a polypeptide—e g, from the "O" antigen of *Bacterium typhosum* it becomes a powerful antigen These studies may explain the development of anti-agar immune-body during the immunisation of horses with agar-grown bacterial cultures, for the non-antigenic agar-polysaccharide probably becomes converted to an antigen by linkage with polypeptides derived from the bacterial growth

Mrs Ida Smedley-MacLean, D Sc and Miss Hume have carried on their investigations on the fat-deficiency disease of rats Animals which receive a diet lacking the essential unsaturated fatty acids, linoleic or linolenic become stunted and emaciated, and it seems that this is not due, as had been thought, to an inability to store or to metabolise fat The essential fatty acids are required in order to synthesise more highly unsaturated fatty acids such as arachidonic, without which the animal cannot produce new cells and tissues

The late Prof R Robison, F R S, and Miss Alice Tazelaar attempted to demonstrate the presence of a cycle of phosphorylation in the cartilage of rachitic rats during the earliest stages of healing They were able to do this in some experiments but not in others and suggested that there is still some other unrecognised factor in the chemical changes occurring during bone formation

ENDOCRINOLOGY

The institute has continued its work in endocrinology along several lines Dr V Korenchevsky and his co-workers have studied the effects of gonadectomy and of injections of sex hormones on the thymus They draw attention to the histological similarity between the epithelial structures in thymomata and in the thymus of rats treated with œstrogens but note that the epithelial hyperplasia in no case amounted to tumour formation Despite this, it is clear that œstrogenic hypersecretion must be borne in mind as a possible factor in the formation of thymic tumours It would be interesting to know whether any muscular changes were observed in the treated animals Though the diagnosis of myasthenia gravis in a rat might be somewhat difficult on purely clinical grounds, the histological examination of the muscles for lymphorrhages would be a useful extension of the work The same workers have considered the rôle of œstrogenic hormones in the normal development of he male sex organs and have concluded that added œstrogens produce a very small increase compared with hat produced by increasing the dose of androgens The significance of this is that in practice the synergistic ction of œstrogens when given with androgens can be eglected a conclusion with which most clinicians would gree Scanty as the evidence is for the beneficial effects f androgens in hyperpiesia and prostatic enlargement, here is still less in favour of combining the male and emale sex hormones Further work has been done on he effects of sex hormones on the livers and hearts of ats Taken with previous similar work on kidneys, he results make it clear that androsterone and testoterone esters have an important physiological effect in producing growth of these organs On the other hand, hese substances cause lipoid depletion in the adrenals, while neutralising the pathological effects of œstradiol on he zona reticularis

Sir John Ledingham, F R S, has continued his work on the relation between the sex-hormones and the Foa-Kurloff cell (*J Path Bact* 1940 50, 201, see *Lancet* 940 1, 749) Immature and castrated guineapigs howed a greater response, judged by the number of Foa-Kurloff cells in the circulation, to œstradiol diproionate than to stilbœstrol Immature guineapigs

Continued at foot of next column

THE LISTER INSTITUTE (*continued*)

were injected with emulsions of spleens from œstradiol-treated guineapigs killed at the height of the response when the spleen contains large numbers of Foà-Kurloff cells No clear response was obtained and it is concluded that the substance in the vacuole if of œstrogenic origin, probably represents some inactive breakdown product

Letters to the Editor

COMPENSATION AND IDLENESS

SIR,—The disablement training scheme recently introduced by the Ministry of Labour & National Service for assisting the return to useful civilian employment of disabled persons has much to commend it Circular 2449 makes it clear that the scheme is intended to apply not only to men and women from the Services and civilian air-raid victims but also to those disabled by industrial or civilian accident A very short acquaintance with the scheme shows that, whilst its success with the first two classes of persons is assured, in the accident class and especially in those disabled by industrial accident, serious difficulties arise

Many disabled workmen receive weekly compensation payments over long periods and their return to employment is effectively prevented by the failure of their employers to provide them with suitable work and the unwillingness of insurance companies to settle claims There are hundreds of able-bodied men scattered throughout the country who, although they are capable of doing essential war work, are kept in enforced idleness by the compensation laws Surely it should be possible to devise means whereby outstanding claims could be speedily settled or, where this is impossible, settlement postponed until the end of the war and the men released meantime for essential war work ?

With the present shortage of man power it does seem a pity that so much valuable labour should remain unutilised

Harley Street, W 1 J S BATCHELOR

"IN QUEST OF A CURRICULUM"

SIR,—Perusal of your valuable and instructive educational number this week prompts me to express some views which I have held for the past few years on the teaching, or mis-teaching, of surgery These views are based on a short experience as a teacher on the one hand and from contacts in practice with the products of this teaching on the other We must assume that the qualifying examinations constitute a licence to pursue general practice and they should be designed solely with this end in view We often hear that a particular individual is a good examination coach but an indifferent teacher and this must be considered an indictment of the examination and not of the coach If there is going to be a change in the type of teaching it must be initiated from the examination end For economic reasons students always have, and always will, make the passing of examinations their first consideration and I believe that examiners will have to study more sympathetically the needs of general practice I can only speak with any practical knowledge of the restricted field of surgery but my experience has been that mistakes in general practice derive almost exclusively from insufficient knowledge of the commonest ailments the delay in diagnosis of acute appendicitis, the failure to examine an unconscious patient with a head injury for other injuries, the mismanagement of a Colles fracture and so on I have yet to meet with tragedy consequent on failure to recognise actinomycosis, ignorance of the details of treatment of a tuberculous hip or inability to assess the relative values of perineal excision and abdominoperineal excision in a case of carcinoma of the rectum—all aspects of knowledge liable to be plumbed in the examination hall

Should we not do better to concentrate on the essentials and expect a higher standard in a more restricted field ? Students should have to memorise facts as little as possible, and think and act for themselves as much as possible In surgery I should like to see the requirements of theoretical knowledge narrowed to one set book on the diagnosis, preoperative preparation

A YEAR'S WORK AT THE LISTER INSTITUTE

DESPITE dispersal of staff and temporary transfers to the Services the 47th annual report of work done by members and associated workers of the Lister Institute makes heartening reading at a time when the war has brought research work to a virtual standstill in many of our teaching departments Much of the work to which reference is made in the report has already been published, and only an outline of what is already a condensed record is possible here

BACTERIOLOGY AND IMMUNOLOGY

A considerable part of the bacteriological research has a direct bearing on war-time problems Miss Muriel Robertson D Sc , and Mr James Keppie, M R C V S (see *J Path Bact* July, 1941 p 95), have studied a series of strains of *Clostridium welchii* from war wounds both as regards the optimum conditions for toxin-production and the relationship of toxigenicity in the different strains to the clinical features of the infection While there was some association between high toxigenicity and severity of the clinical lesion—e g most of the strains from cases of gas gangrene gave a high toxin yield—yet poorly toxigenic strains could cause gas gangrene and highly toxigenic strains were isolated from non-gangrenous infections It is true that the local conditions in the wound are all-important in the ætiology of gas gangrene but a study of the degree of capsulation (cf Butler *Med J Aust* 1941, 1, 33) and of the production of hyaluronidase by strains of *Cl welchii* from war wounds might throw light on other possible factors affecting the virulence of the organisms A study of the enzymic content of *Cl welchii* toxin by Miss M G Macfarlane Ph D , and Mr B C J G Knight, D Sc , has brought to light a lecithinase which hydrolyses egg-yolk lecithin with the production of neutral fat and a water-soluble phosphorus compound This finding obviously explains the Nagler reaction—the opalescence produced in human serum or diluted egg-yolk by toxigenic strains of *Cl welchii*—and may lead to an exact quantitative assay of toxin production by *Cl welchii* by a phosphorus estimation Dealing with another of the pathogenic anaerobes, Dr G H Eagles has found that the flocculation reaction cannot be substituted for in vivo tests in the standardisation of tetanus antitoxin

The treatment of bacillary dysentery has again assumed importance Miss Dorothy Steabben, Ph D , has prepared experimentally a protective antibacterial serum against the Shiga bacillus, and it may prove advantageous in treatment to combine such an antisomatic serum with the ordinarily used Shiga antitoxin With the help of the ultracentrifuge and electrophoresis apparatus, progress has been made in the identification of the active globulin fractions of antitoxic sera In the purification and concentration of antitoxins by pepsin-digestion and heat-denaturation, Mr R A Kekwick, M Sc , and Mr B R Record, Ph D , found that the resulting loss in potency was associated with the disappearance of the γ-globulin which has the short flocculation time and high in-vivo/in-vitro ratio characteristic of an " avid " serum Since avidity in the antibody may be important in the treatment of the more severe diphtheritic infections, over-refinement of antitoxin may as recently suggested by O'Meara, lead to therapeutic inefficiency The γ-globulin can be easily separated from human serum by salt fractionation but this method largely fails with horse serum, so that some other method for isolating this possibly important fraction in antitoxin needs to be devised Human serum reconstituted from the dried state after freezing usually has an opalescent appearance Dr A S McFarlane has found this phenomenon to be due to the coating of the finely divided fat-globules by a layer of β-globulin, and the milkiness can only be got rid of by treating with ether at a low temperature when globulin and fat become separated

Dr H L Schutze showed that spacing the two doses of a mouse-typhoid vaccine to a month's interval did not affect its protective value against artificial infection, and he concluded that it is safe to give T A B vaccine combined with tetanus toxoid in two doses at 4–6 weeks' interval Clinical trials with the agglutinin-response as the measure of protective value are in confor with this view The work of Mr A Felix, D Sc , a new T A B vaccine in which the Vi antigen is prese by killing the bacilli with alcohol and storing them in has already been discussed (*Lancet*, 1941, 1, 543) whi Dr Douglas McClean has recently reviewed his own an others' work on the bacterial production of diffu factor, now known to be a mucolytic enzyme call hyaluronidase (*Lancet*, 1941, 2, 797)

NUTRITION

Work has continued on the standardisation of vitami A and E For vitamin E, it is recommended that *dl* tocopheryl acetate should now be adopted temporari by the British Empire and the United States, since i acceptance by the International Conference on Vitam Standardisation is at the moment impossible Public tion of the results of the tests which have led to th adoption of the standards for vitamins B_1 and D hav likewise had to be postponed

Mr T F Macrae D Sc , and his collaborators hav continued their work on the factors in the vitamin complex required by rats Apart from riboflavin an vitamin B_6, the rat requires the " filtrate factor ", this i now known to contain three components, one of which i pantothenic acid The chemistry of the remaining two components is rapidly being worked out and active concentrates of them, each free from the other, have been prepared Dr Macrae and Miss Alice Copping, M Sc , have devised new methods for the estimation of vitamin B_6 and of the filtrate-factor complex They have also used with success their method for estimating riboflavin in foodstuffs Dr M M El Sadr has completed his studies on the ocular changes produced in rats by deficiency of riboflavin These changes are, in order of appearance, conjunctivitis, blepharitis, corneal opacity and sometimes cataract All except the last are cured by the administration of the vitamin Miss Harriette Chick, D Sc , and Dr El Sadr have examined the effect of deficiency of vitamin B_6 and of filtrate factor on the blood of rats Deficiency of B_6 results in a microcytic anæmia It is suggested that the rat might prove of value as a test animal in the study of human anæmia

A comparison has been made of the nutritive value of white and wholemeal flours and of bread baked from them Dr Chick and Mrs C E Work, Ph D , find that the proteins of wholemeal flour show a distinct superiority (30% greater increase in weight in rats) over those of white flour Dr Chick has also shown with rats that wholemeal flour is a much richer source of vitamins of the B_2 group Digestibility tests on six human volunteers organised by Dr Macrae, showed that a somewhat higher proportion of energy and of nitrogen were lo in the fæces when wholemeal bread was being consumed instead of white , the results indicate that in the manufacture of white flour of 73% extraction some 20% of the total available energy and 27% of the nitrogen are left in the offals None of the six subjects was adversely affected by the wholemeal bread of which each consumed 2–2½ lb daily

Miss E M Hume and Miss H Henderson Smith have studied the fat-soluble pigments in flour They find that only a small part of the yellow pigment is biologically active as provitamin A There is no difference in the amount of this in wholemeal and in white flour

Since yeast can be grown comparatively easily, and since it is an excellent source of the B vitamins, its consumption might be of value in maintaining the national health during the war A series of tests have therefore been carried out on a specimen of yeast (*Torula utilis*) which might be used for this purpose Miss Copping has shown that neither the composition of the culture medium nor the subsequent processing of the yeast appreciably affected the quantity of the B_2 vitamins White flour to which had been added 2½% of *Torula utilis* was found by Dr Chick to be as rich a source of vitamins of the B group as wholemeal flour Dr Macrae has noted that even twice this amount of yeast does not seriously affect the palatability of white or wholemeal breads He has also shown, in collaboration with workers at the Institute of Animal Pathology at Cambridge that the protein of *Torula utilis* was of high nutritive value, comparable with a first-class protein such as casein in supplementing biologically poor proteins

Mr S S Zilva, D Sc has continued his work on the tamin-C content of fruits and vegetables With Mr B Crane, he has shown that the amount of the vitamin tomatoes does not depend to any great extent on the riety but that tomatoes grown in the open contain uch more vitamin C than those grown under glass

BIOCHEMISTRY

Mr W T D Morgan D Sc, *continuing his researches* n the antigenic complex of the Shiga dysentery bacillus, as by different methods isolated the specific polysaccharide of the organism in undegraded form This ubstance is not by itself capable of stimulating the ormation of antibody but in combination with a polypeptide—e g from the "O" *antigen of Bacterium yphosum* it becomes a powerful antigen These studies may explain the development of anti-agar immune-body during the immunisation of horses with agar-grown bacterial cultures, for the non-antigenic agar-polysaccharide probably becomes converted to an antigen by linkage with polypeptides derived from the bacterial growth

Mrs Ida Smedley-MacLean, D Sc, and Miss Hume have carried on their investigations on the fat-deficiency disease of rats Animals which receive a diet lacking the essential unsaturated fatty acids linoleic or linolenic become stunted and emaciated, and it seems that this is not due, as had been thought, to an inability to store or to metabolise fat The essential fatty acids are required in order to synthesise more highly unsaturated fatty acids such as arachidonic, without which the animal cannot produce new cells and tissues

The late Prof R Robison, F R S and Miss Alice Tazelaar attempted to demonstrate the presence of a cycle of phosphorylation in the cartilage of rachitic rats during the earliest stages of healing They were able to do this in some experiments but not in others and suggested that there is still some other unrecognised factor in the chemical changes occurring during bone formation

ENDOCRINOLOGY

The institute has continued its work in endocrinology along several lines Dr V Korenchevsky and his co-workers have studied the effects of gonadectomy and of injections of sex hormones on the thymus They draw attention to the histological similarity between the epithelial structures in thymomata and in the thymus of rats treated with œstrogens but note that the epithelial hyperplasia in no case amounted to tumour formation Despite this, it is clear that œstrogenic hypersecretion must be borne in mind as a possible factor in the formation of thymic tumours It would be interesting to know whether any muscular changes were observed in the treated animals Though the diagnosis of myasthenia gravis in a rat might be somewhat difficult on purely clinical grounds, the histological examination of the muscles for lymphorrhages would be a useful extension of the work The same workers have considered the rôle of œstrogenic hormones in the normal development of the male sex organs and have concluded that added œstrogens produce a very small increase compared with that produced by increasing the dose of androgens The significance of this is that in practice the synergistic action of œstrogens when given with androgens can be neglected, a conclusion with which most clinicians would agree Scanty as the evidence is for the beneficial effects of androgens in hyperpiesia and prostatic enlargement, there is still less in favour of combining the male and female sex hormones Further work has been done on the effects of sex hormones on the livers and hearts of rats Taken with previous similar work on kidneys, the results make it clear that androsterone and testosterone esters have an important physiological effect in producing growth of these organs On the other hand these substances cause lipoid depletion in the adrenals, while neutralising the pathological effects of œstradiol on the *zona reticularis*

Sir John Ledingham F R S, has continued his work on the relation between the sex-hormones and the Foa-Kurloff cell (*J Path Bact* 1940 50, 201, see *Lancet* 1940 1, 749) Immature and castrated guineapigs showed a greater response, judged by the number of Foa-Kurloff cells in the circulation, to œstradiol dipropionate than to stilbœstrol Immature guineapigs

Letters to the Editor

COMPENSATION AND IDLENESS

SIR,—The disablement training scheme recently introduced by the Ministry of Labour & National Service for assisting the return to useful civilian employment of disabled persons has much to commend it Circular 2449 makes it clear that the scheme is intended to apply not only to men and women from the Services and civilian air-raid victims but also to those disabled by industrial or civilian accident A very short acquaintance with the scheme shows that whilst its success with the first two classes of persons is assured, in the accident class and especially in those disabled by industrial accident serious difficulties arise

Many disabled workmen receive weekly compensation payments over long periods and their return to employment is effectively prevented by the failure of their employers to provide them with suitable work and the unwillingness of insurance companies to settle claims There are hundreds of able-bodied men scattered throughout the country who although they are capable of doing essential war work, are kept in enforced idleness by the compensation laws Surely it should be possible to devise means whereby outstanding claims could be speedily settled or, where this is impossible, settlement postponed until the end of the war and the men released meantime for essential war work ?

With the present shortage of man power it does seem a pity that so much valuable labour should remain unutilised

Harley Street, W 1 J S BATCHELOR

"IN QUEST OF A CURRICULUM"

SIR,—Perusal of your valuable and instructive educational number this week prompts me to express some views which I have held for the past few years on the teaching, or mis-teaching, of surgery These views are based on a short experience as a teacher on the one hand and from contacts in practice with the products of this teaching on the other We must assume that the qualifying examinations constitute a licence to pursue general practice and they should be designed solely with this end in view We often hear that a particular individual is a good examination coach but an indifferent teacher and this must be considered an indictment of the examination and not of the coach If there is going to be a change in the type of teaching it must be initiated from the examination end For economic reasons students always have, and always will, make the passing of examinations their first consideration and I believe that examiners will have to study more sympathetically the needs of general practice I can only speak with any practical knowledge of the restricted field of surgery but my experience has been that mistakes in general practice derive almost exclusively from insufficient knowledge of the commonest ailments the delay in diagnosis of acute appendicitis, the failure to examine an unconscious patient with a head injury for other injuries, the mismanagement of a Colles fracture and so on I have yet to meet with tragedy consequent on failure to recognise actinomycosis, ignorance of the details of treatment of a tuberculous hip or inability to assess the relative values of perineal excision and abdomino-perineal excision in a case of carcinoma of the rectum—all aspects of knowledge liable to be plumbed in the examination hall

Should we not do better to concentrate on the essentials and expect a higher standard in a more restricted field ? Students should have to memorise facts as little as possible, and think and act for themselves as much as possible In surgery I should like to see the requirements of theoretical knowledge narrowed to one set book on the diagnosis, preoperative preparation

THE LISTER INSTITUTE (*continued*)

were injected with emulsions of spleens from œstradiol-treated guineapigs killed at the height of the response when the spleen contains large numbers of Foà-Kurloff cells No clear response was obtained and it is concluded that the substance in the vacuole if of œstrogenic origin, probably represents some inactive breakdown product

A YEAR'S WORK AT THE LISTER INSTITUTE

DESPITE dispersal of staff and temporary transfers to the Services, the 47th annual report of work done by members and associated workers of the Lister Institute makes heartening reading at a time when the war has brought research work to a virtual standstill in many of our teaching departments Much of the work to which reference is made in the report has already been published and only an outline of what is already a condensed record is possible here

BACTERIOLOGY AND IMMUNOLOGY

A considerable part of the bacteriological research has a direct bearing on war-time problems Miss Muriel Robertson, D Sc, and Mr James Keppie, M R C V S (see *J Path Bact* July, 1941, p 95), have studied a series of strains of *Clostridium welchii* from war wounds both as regards the optimum conditions for toxin-production and the relationship of toxigenicity in the different strains to the clinical features of the infection While there was some association between high toxigenicity and severity of the clinical lesion—e g most of the strains from cases of gas gangrene gave a high toxin yield—yet poorly toxigenic strains could cause gas gangrene and highly toxigenic strains were isolated from non-gangrenous infections It is true that the local conditions in the wound are all-important in the ætiology of gas gangrene but a study of the degree of capsulation (cf Butler *Med J Aust* 1941, 1, 33) and of the production of hyaluronidase by strains of *Cl welchii* from war wounds might throw light on other possible factors affecting the virulence of the organisms A study of the enzymic content of *Cl welchii* toxin by Miss M G Macfarlane Ph D, and Mr B C J G Knight, D Sc, has brought to light a lecithinase which hydrolyses egg-yolk lecithin with the production of neutral fat and a water-soluble phosphorus compound This finding obviously explains the Nagler reaction—the opalescence produced in human serum or diluted egg-yolk by toxigenic strains of *Cl welchii*—and may lead to an exact quantitative assay of toxin production by *Cl welchii* by a phosphorus estimation Dealing with another of the pathogenic anaerobes, Dr G H Eagles has found that the flocculation reaction cannot be substituted for in vivo tests in the standardisation of tetanus antitoxin

The treatment of bacillary dysentery has again assumed importance Miss Dorothy Steabben, Ph D, has prepared experimentally a protective antibacterial serum against the Shiga bacillus, and it may prove advantageous in treatment to combine such an antisomatic serum with the ordinarily used Shiga antitoxin With the help of the ultracentrifuge and electrophoresis apparatus, progress has been made in the identification of the active globulin fractions of antitoxic sera In the purification and concentration of antitoxins by pepsin-digestion and heat-denaturation, Mr R A Kekwick, M Sc and Mr B R Record, Ph D, found that the resulting loss in potency was associated with the disappearance of the γ-globulin which has the short flocculation time and high in-vivo/in-vitro ratio characteristic of an "avid" serum Since avidity in the antibody may be important in the treatment of the more severe diphtheritic infections, over-refinement of antitoxin may, as recently suggested by O'Meara, lead to therapeutic inefficiency The γ-globulin can be easily separated from human serum by salt fractionation but this method largely fails with horse serum, so that some other method for isolating this possibly important fraction in antitoxin needs to be devised Human serum reconstituted from the dried state after freezing usually has an opalescent appearance Dr A S McFarlane has found this phenomenon to be due to the coating of the finely divided fat-globules by a layer of β-globulin, and the milkiness can only be got rid of by treating with ether at a low temperature when globulin and fat become separated

Dr H L Schutze showed that spacing the two doses of a mouse-typhoid vaccine to a month's interval did not affect its protective value against artificial infection, and he concluded that it is safe to give T A B vaccine combined with tetanus toxoid in two doses at 4–6 weeks' interval Clinical trials with the agglutinin-response as the measure of protective value are in confor with this view The work of Mr A Felix, D Sc, a new T A B vaccine in which the Vi antigen is prese by killing the bacilli with alcohol and storing them in has already been discussed (*Lancet*, 1941, 1, 543) whil Dr Douglas McClean has recently reviewed his own and others' work on the bacterial production of diffu factor, now known to be a mucolytic enzyme call hyaluronidase (*Lancet*, 1941, 2, 797)

NUTRITION

Work has continued on the standardisation of vitamin A and E For vitamin E, it is recommended that *dl* tocopheryl acetate should now be adopted temporarily by the British Empire and the United States, since it acceptance by the International Conference on Vitamin Standardisation is at the moment impossible Publication of the results of the tests which have led to the adoption of the standards for vitamins B_1 and D have likewise had to be postponed

Mr T F Macrae D Sc, and his collaborators have continued their work on the factors in the vitamin B_2 complex required by rats Apart from riboflavin and vitamin B_6, the rat requires the "filtrate factor", this i now known to contain three components one of which i pantothenic acid The chemistry of the remaining two components is rapidly being worked out and active concentrates of them, each free from the other, have been prepared Dr Macrae and Miss Alice Copping, M Sc have devised new methods for the estimation of vitamin B_6 and of the filtrate-factor complex They have also used with success their method for estimating riboflavin in foodstuffs Dr M M El Sadr has completed his studies on the ocular changes produced in rats by deficiency of riboflavin These changes are, in order of appearance, conjunctivitis, blepharitis, corneal opacity and sometimes cataract All except the last are cured by the administration of the vitamin Miss Harriette Chick, D Sc, and Dr El Sadr have examined the effect of deficiency of vitamin B_6 and of filtrate factor on the blood of rats Deficiency of B_6 results in a microcytic anæmia It is suggested that the rat might prove of value as a test animal in the study of human anæmias

A comparison has been made of the nutritive value of white and wholemeal flours and of bread baked from them Dr Chick and Mrs C E Work, Ph D, find that the proteins of wholemeal flour show a distinct superiority (30% greater increase in weight in rats) over those of white flour Dr Chick has also shown with rats that wholemeal flour is a much richer source of vitamins of the B_2 group Digestibility tests on six human volunteers, organised by Dr Macrae, showed that a somewhat higher proportion of energy and of nitrogen were lost in the fæces when wholemeal bread was being consumed instead of white, the results indicate that in the manufacture of white flour of 73% extraction some 20% of the total available energy and 27% of the nitrogen are left in the offals None of the six subjects was adversely affected by the wholemeal bread of which each consumed 2–2½ lb daily

Miss E M Hume and Miss H Henderson Smith have studied the fat-soluble pigments in flour They find that only a small part of the yellow pigment is biologically active as provitamin A There is no difference in the amount of this in wholemeal and in white flour

Since yeast can be grown comparatively easily, and since it is an excellent source of the B vitamins, its consumption might be of value in maintaining the national health during the war A series of tests have therefore been carried out on a specimen of yeast (*Tolura utilis*) which might be used for this purpose Miss Copping has shown that neither the composition of the culture medium nor the subsequent processing of the yeast appreciably affected the quantity of the B_2 vitamins White flour to which had been added 2½% of *Torula utilis* was found by Dr Chick to be as rich a source of vitamins of the B group as wholemeal flour Dr Macrae has noted that even twice this amount of yeast does not seriously affect the palatability of white or wholemeal breads He has also shown, in collaboration with workers at the Institute of Animal Pathology at Cambridge that the protein of *Torula utilis* was of high nutritive value, comparable with a first class protein such as casein in supplementing biologically poor proteins

A GLYCERIN-GELATIN BASE OR IRRADIATION DERMATITIS AND BURNS

PERCIVAL P. COLE
M.B BIRM, F.R C.S
CONSULTING SURGEON ROYAL CANCER HOSPITAL; SURGEON, E.M.S

M LEDERMAN,
M.B LOND, D M.R.E
RADIUM THERAPIST TO THE HOSPITAL

THE cutaneous phenomena observed after radium or -ray treatment can be subdivided into two groups—ute and chronic. The first includes the reactions nging from erythema to a moist desquamation which re comparable to a first or second degree burn. The cond includes the persistent painful ulceration termed n X-ray or radium "burn" and various other sequelæ f treatment—e g telangiectases, atrophy chronic dema and hyperkeratosis. Apart from the cosmetically unwelcome ones, such as atrophy and œdema, the more pernicious sequelæ are, thanks to improvement of apparatus and technique not commonly seen nowadays, and the acuteness of any reaction can be controlled by suitable attention to treatment and dosage.

It has been customary since the earliest days of radiotherapy to apply unguents to these raw areas, but of recent years tannic-acid jelly has achieved some popularity. Whereas oily substances or unguents tend to obstruct drainage and spread infection a jelly forms its own dressing and has none of these disadvantages. It was found, however, that when used on skin surfaces that were normally prone to movement such as near the mouth on the neck or in the groin folds it was impossible to obtain a crust of even thickness. Owing to the irregularity of distribution and lack of pliability the crust fissured readily caused discomfort and required constant renewal. Some degree of infection was also encountered in an appreciable number of cases. The tendency to crack was exhibited, though in lesser degree by flavine when immobilisation of the area treated was either impossible or inadvisable. An attempt was made, therefore to find means whereby pliability could be increased. Finally the desired result was attained by the addition of a glycerin-gelatin base. The composition of this application is as follows —

℞ Proflavine gr 4⅘
Glycerin suppository (mass) gr 375
Distilled water ad 10 fl oz

Dissolve the proflavine in the water, making a solution of 1 in 1000, warm and add the glycerin suppository mass, when dissolved strain through gauze. Apply from an all-glass spray.

An extensive trial of this simple preparation has been carried out in the radium department of the Royal Cancer Hospital in cases where the skin shows moist desquamation—i e, loss of superficial layers of the true skin. We have been sufficiently impressed by its efficacy to justify us in bringing it to general notice. Its advantages are —

1 It is antiseptic—a point of importance when it is realised that irradiated skin resists infection but feebly.
2 The crust is of even thickness, flexible and forms its own dressing, the solution is easy to apply by means of a glass spray.
3 It is cheap and simple to make.

For cases which show an idiosyncrasy to proflavine, gentian violet, methylene-blue, brilliant green, or a combination of them, can replace the proflavine. The sole objection to the application is that it contains glycerin which is on the list of drugs in the use of which we are asked to exercise strict economy. We have been unable to find a satisfactory substitute.

We are indebted to Mr J H. Wood, pharmacist to the Royal Cancer Hospital, for advice and technical assistance.

BOMBS AND MILK

Rowland and Hinks[1] have studied the yield and the composition of the milk from herds near to which bombs had dropped. In some cases the yield fell, in others it remained unchanged but in all cases the milk immediately after the incident did not show any significant difference in composition from that obtained several days later. In one instance milk had been taken the day before the bombing for a partial analysis and this also confirmed the findings that bombing caused no change in the composition. The defence in prosecutions for the sale of adulterated milk has already shown a tendency to allege that the poor quality was due to the herds having been bombed and these investigations were undertaken to examine the validity of such a contention.

MAN OR SPIDER

MOST poets begin young and to publish a slender volume of verse in the early twenties used to be considered comme-il-faut. Indeed Hardy once said he thought that the shortest way to good prose was by the route of good verse. Dr. David Stafford-Clark is a poet living in swift exciting times and he has made the most of his chances.[1] His glimpses of May on the Cherwell chapel at Oxford his mannered valentines epitaphs and sonnets already have the gentle charm of something we—and he—have lost. But even in 1937 contradictions of the world amazed him. In his lines to the black widow spiders at the Zoo doomed to die when the first bombs fall he says

'. . For it would be dreadful
If, living through the gas and bombs his fellow men have dropped
Someone should perish
Of your pathetic poison "

His address to the modern poets who cannot bear any slavishly direct attempt to say anything is a withering blast of sarcasm.

In the later poems of the war Dr Stafford-Clark shows generous indignation at wanton pain and ugliness and an understanding of the exaltation of battle which exists alongside it

" the exultant lust
To destroy and risk destruction
Suddenly canonized by war "

SIGNIFICANCE OF FEAR

IN a recent Honyman Gillespie lecture in Edinburgh Prof D K Henderson said that the trend of medicine in general had been towards the protection of the unfit but emotional and instinctive needs had largely been left to chance. This neglect was followed by the occurrence of nervous and mental disease. There was a fatalistic outlook on the inevitability of mental disease and consequently a state of therapeutic nihilism. Modern psychiatry was striving to demonstrate that this attitude was false and that much valuable preventive or early curative work was possible. Fear, which was one of the most widespread human emotions could be both good and bad. Fear might provide for safety, as in the self-protection behaviour of animals and in the human it might also provide for social integration particularly the fear of punishment or ridicule. Fear resulted in disturbance of the autonomic nervous system with many physical manifestations and might lead to disorders which could not be cured by the physician or surgeon unless the underlying anxiety were removed. It was always to be remembered that a man might demonstrate bravery owing to his fear of being afraid and it was fear itself which was the fundamental cause of the adoption of superstitious practices. Professor Henderson believed that fear was more social than sexual in its origin and that it depended on separation from the mother both in children and adults. Fear and loneliness went hand in hand. In children fears and anxieties which might subsequently give rise to serious nervous disease were often initiated superficially by casual remarks of maids nurses or mothers. He criticised our educational system in which there was no attempt to differentiate between those children who were able to stand its rigours and those who by their innate constitution were unable to do so. He believed that this was important in the production of nervous and mental illness which might be avoided if more care were exercised in the choice of schools and in assessment of the stability of the child. Fear states initiated in childhood persisted into adult life usually in highly sensitive artistic people who disliked loneliness and might come to use alcohol and after-treatment of a limited number of disorders, written or at least approved by a competent board of teachers Outside the limits of this set book no other theoretical knowledge would be expected Students who would otherwise waste their time reading about problems which they are unlikely to meet in general practice would then have more time to absorb the atmosphere of the wards and would feel that time spent in the wards was not jeopardising their chances of passing their examinations, as some anxious students feel today They should attend the operating theatre only for the study of living pathology and to confirm the significance of physical signs which they themselves have elicited in the ward For the most part a student would make a better doctor if he spent the time at present devoted to watching operations in going for a walk in the country Examiners in the qualifying examinations should be continually on their guard against asking questions outside the scope of these essential requirements The rumour circulating in a medical school that even one examiner is prone to this vice will at once send students scuttling to the library to look up the pathology of brain tumours and Paget's disease of the nipple, the treatment of epithelioma of the anus and the development of hare-lip

Finally I should like to see introduced into the paper more questions such as these

Discuss in detail the technique of dressing (*a*) a wound healing by first intention, (*b*) an open infected wound

Describe the clinical picture of any abdominal emergency you have seen recently

The wife of a working man with a large family is found to have a moderate sized inguinal hernia Discuss what advice you, as her family doctor, would give her if (*a*) it was decided to operate upon this hernia, (*b*) she was to be supplied with a truss

Write an imaginary report for an insurance company on a patient injured in a motor car accident

Nuffield House, Guy's Hospital H J B ATKINS

BACTERIOLOGY OF IMPETIGO CONTAGIOSA

SIR,—Dr Cruickshank, while endorsing my plea for a more intensive investigation of impetigo contagiosa, makes some statements to which I should like to reply

Epidemiological data —There is a misconception implicit in this paragraph Dr Cruickshank states that impetigo "is not apparently a highly contagious disease" In fact, impetigo contagiosa cannot infect intact skin, but in the presence of any flaw in the skin surface—traumatic, by falls or scratching, or excoriations due to a running nose, or a herpes febrilis or labialis—impetigo is most contagious

I have several times heard the suggestion of some relationship between scarlet fever and impetigo contagiosa, but in the course of six years during which some thousands of cases of impetigo contagiosa have been noted I have found no trace of relationship Were the vaccinia-smallpox type of relationship present, scarlet fever should surely by now have disappeared

"Nephritis has been noted as a complication of impetigo" I know of one reference in an American journal which I was unable to obtain The association must be very rare It is however not uncommon for patients who are sensitive to white precipitate ointment to develop albuminuria and general anasarca while undergoing treatment for impetigo contagiosa If the presence of nephritis argues for a scarlatinal type of streptococcal agent, then the absence of it from thousands of cases of very severe impetigo contagiosa may suggest that the hæmolytic streptococci found are not causal

Treatment —I cannot understand the difficulties experienced in treating this complaint if three rules are observed

1 Never scratch
2 Never remove scabs
3 Never let water touch the skin

White precipitate ointment, calamine lotion or talc powder are my medicaments of choice, but probably almost anything else not too wetting would do equally well In the presence of seborrhœa or mercury sensitivity, calamine lotion is preferable Simple Elastoplast occlusion is often very convenient The only real difficulties I have encountered are seborrhœic skins, and impetigo contagiosa on an œdematous leg formed a large chronic ulcer)

Bacteriology —The consensus of opinion today may in favour of a hæmolytic streptococcus as causal agent, but I had hoped Dr Cruickshank was going to sub the premiss to re-examination Unfortunately he quite arbitrarily selects the 15 streptococcal cultures recovered from 23 cases as causal, whilst rejecting the 18 staphylococcal growths as secondary invaders May I repeat my plea for a search for a *constant* causal organism in impetigo It may be a streptococcus, a staphylococcu a diplococcus, a pleomorphic organism, a filter passing virus, a mite, a worm or a spirochæte, but it will be recoverable from all cases of impetigo contagiosa, and will probably have the following characters

1 It will produce impetigo contagiosa in humans
2 It will not produce impetigo contagiosa in animals
3 It will fail to produce erysipelas, scarlet fever and boils
4 It will not be recoverable from erysipelas, scarlet fever and boils
5 It will produce no, or very little, local or general immunity

Were I a betting man I should put my shirt on the very large diplococcus, often intracellular in the pu cells, constantly found in the direct smears, and fir *described in 1897 by Balzer and Griffon*

Beaminster, Dorset R E HOPE SIMPSON

Medical News

Epsom College

The council of the college will shortly proceed to award St Anne's scholarships to girls attending Church of England schools Candidates must be fully 9 and under 16 years of age, and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than 5 years The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected The conjoint committee will in November award a Challice annuity of £32 per annum to a qualified medical man who, on account of old age, has been compelled to retire and who is in need Forms of application can be had from the secretary's office, Epsom College, Surrey, and must be returned by Oct 14

Medical Honours

The George medal has been awarded to Mr R W Wye resident surgical officer at Salford Royal Hospital, and to Dr Leonard Findlay, medical superintendent of Mill Road Infirmary, Liverpool

Naval Casualties

In a recent casualty list T/Surgeon Lieutenant A T Leggate, M B Lpool, R N V R, is posted as missing, presumed killed Surgeon Lieut Commander William Greave M B Leeds, R N, is reported to be a prisoner of war

Tavistock Clinic

A luncheon in celebration of the 21st anniversary of the clinic will be held at Grosvenor House, Park Lane, London, W 1, on Monday, Sept 29, at 1 P M Further information may be had from the secretary of the clinic, at Westfield College, Kidderpore Avenue, N W 3

Liquid Paraffin Emulsions

A defence regulation is shortly to be issued prohibiting the manufacture of any emulsion of liquid paraffin containing more than 25% by volume of liquid paraffin Some proprietary emulsions contain proportions as high as 65%, but the Therapeutic Requirements Committee are satisfied that a 25% emulsion is as effective as the pure oil The National War Formulary, which is now in proof, will contain a 25% emulsion

Lecture on Industrial Health

The Henry George School of Economics have arranged six lectures on economic problems of today under the title Fact Behind the News In the series Dr H B Morgan, M P, will deal with industrial health on Tuesday, Sept 23, at 6 P M The lectures will all be held at the school, 13, Suffolk Street, Pall Mall, S W 1

Corrigendum —In Dr J D Robertson's letter of Sept 6, p 294, col 2, for "vitamin storage work" read "calcium storage work"

ENURESIS
TREATED BY URETHRAL DILATATION *

H P WINSBURY-WHITE M D Edin., F R C S
UROLOGIST TO THE PRINCESS ELIZABETH OF YORK HOSPITAL FOR CHILDREN, SHADWELL

IN this paper I have analysed 310 cases of enuresis examined and treated by me in the Princess Elizabeth Hospital In 98% there was a history of at least one of the exanthemata, which did not always precede the enuresis, in 16% the enuresis came on immediately after an infectious illness, as a rule one of the exanthemata, and in many others the enuresis became worse after measles, scarlet fever or some other infective condition. In 49% of the cases it began during infancy and in 84% before the end of the sixth year, 61% of the patients were girls Cases could be grouped according to symptoms as follows

Enuresis by day and night and daily frequency	40%
Nocturnal enuresis and daily frequency	35%
Nocturnal enuresis only	23%
Diurnal enuresis and daily frequency	2%

There were variations from these four main types and it was not uncommon for symptoms to alter as time went on Some patients became subject to attacks of cystitis or acute pyelitis Thirst without glycosuria was present in some, doubtless owing to the polyuria which was often present

FINDINGS ON EXAMINATION

Local inflammation —Inflammation of the external meatus was not uncommon in the boys under 3 years It was only seen in circumcised children and was commonly associated with constriction of the meatus In the uncircumcised, when there was retained smegma beneath adhesions there was always mild œdema of the external urinary meatus Vulvitis was present in 57% of the girls and was usually chronic I found it important to examine the vulva in good daylight, since artificial light made the hyperæmic areas difficult to detect Inflammation was commonly found in patches localised to the sulci at the junction of the hymen and vestibule with the labia minora ; it occurred in relation to the mouths of the glands in this region and to the urethral orifice, on either side of which a Skene's para-urethral gland was sometimes affected Less commonly the inflammation involved the labia minora, hymen and vestibule sometimes causing a scanty discharge apparent as slight moisture on the skin surfaces adjacent to the labia majora The vulvitis was not accompanied by vaginitis, in contrast with the hyperæmia of the vulva the mucous membrane of the posterior vaginal wall was pale and healthy looking Smears and cultures from vulva and urethra always gave a mixed group of organisms In one case diphtheritic membrane was present on the labia minora, from which Klebs-Löffler bacilli were obtained In a few older girls the cervix was examined and found to be chronically inflamed Smears and cultures gave results similar to those from smears taken from the vulva, except in one case not in this series where gonococci were identified

Hydrocele chronic epididymitis and non-purulent urethral discharge were noted in some of the boys in addition to the conditions described

Calibre of urethra —Working with metal sounds calibrated on the French scale I was able, after making numerous observations, to work out the average normal calibre of the urethra according to age By noting the size of the largest instrument which would lie in the urethra without being gripped I obtained these figures

Age (years)	Size of sound (Charrière)	Age (years)	Size of sound (Charriere)
2	10	10	18
4	12	12	20
6	14	14	22
8	16		

Allowance would sometimes have to be made for the fact that a child was large or small in relation to age More striking departures from the normal included generalised constriction of the urethra and its inability to dilate In 27% of boys the external meatus was obviously constricted Circumcised children were more often afflicted in this way than uncircumcised There were many lesser degrees of narrowing, some very slight but important when urethral dilatation was undertaken, since meatotomy had to be performed first Actually meatotomy was necessary in over 70% of boys requiring dilatation Construction of the meatus was rare in girls, and in every such case the meatus would only admit a much smaller sound than that normally taken by other children of the same age

Cystoscopy was carried out in 220 cases The posterior urethra was inspected in 173 cases For cystoscopy the child should be in the lithotomy position so that a good view is obtainable of the neck of the bladder, with the patient in this position a satisfactory view can also be obtained with the cystoscope of the floor of the posterior urethra In boys it is safer to pass metal instruments with the child lying flat, the thighs can subsequently be plexed on the abdomen I prefer the child to remain flat on the back while the posterior urethroscope is used Of the 220 cystoscoped, 70% showed signs of inflammation on the front of the trigone, and at the internal urinary meatus While of the 173 cases of which the posterior urethra was examined, 76% showed definite posterior urethritis There was usually no inflammation of the general vesical mucosa, but a fluffy appearance on the front of the trigone and œdema of the internal meatus were common In boys, polypi or granular patches were noted on the verumontanum or in the prostatic sinuses In girls polypi or inflammatory hillocks on any part of the circumference of the posterior urethra were common As the instrument was withdrawn the anterior urethra was inspected and always showed inflammatory changes when the posterior urethra was inflamed I have found similar evidence of inflammation of the bladder-neck and urethra in children with chronic frequency without enuresis and conclude that symptoms in both groups are due to such inflammation, especially since 76 of my enuresis cases had chronic frequency as well

Urine —Catheter specimens of urine were examined in 250 cases, but evidence of infection was found in only 15% In 108 cases the average pH was 4 4, the lowest reading being 3 8 and the highest 9 7 Thus enuresis does not seem to depend on acidity Several cases with chronic coliform infection had so much dilatation in the upper urinary tract that the infection was obviously a complication of urinary stasis, and where the dilatation was without remedy so was the infection

Urography —Of the enuresis cases, 150 were examined by urography and 60% showed abnormalities in the upper urinary tract which, though slight, indicated early changes due to the chronic inflammatory process below. They included mild dilatation of calyces, pelvis and ureter; poor renal shadow due to diminished renal function, and poor renal shadow due to renal hyperactivity The presence of mild dilatation on one side is established by contrasting the two sides Normal relaxation of the musculature cannot explain a dilatation which appears consistently in a series of films Evidence of impaired function is seen in the absence of definition in a particular group of calyces throughout the whole series, when there is no gas in the overlying bowel such an appearance suggests that the papillæ draining into those calyces are not doing their work. When any alternative explanation seriously arises, instrumental pyelography will settle the question Dilatation of the ureter is often present, indicated not only by a widening of the whole or a part of the channel but also by lengthening which produces a loop or sometimes two loops Slight localised dilatations not dependent on an obstruction are difficult to explain except as part of an inflammatory phenomenon, especially where subsequent urograms show that the dilatation has disappeared More than 1 oz of residual urine was present in 5% of cases Several children had quantities of less than an ounce as a means of maintaining a uniform state. They came to be dominated by unreal fears for health, life and so on, and at first they repressed their fears and put up a good show. This was usually because of the additional fear that they would be ridiculed or thought mad if they spoke freely. They usually avoided speaking of their fears even after these had been present for many years and a tremendous continual nervous conflict developed which was more fatiguing than the heaviest physical exertion. It was demonstrated externally by asthenia, lack of concentration and loss of spontaneousness, together with physical features which might be referred, for example, to the heart or the digestive system. Doctors should try to obtain the psychological background of their patients, particularly those suffering from psychoneurosis. It was necessary to know the background against which their symptoms had developed before modification or cure could be obtained, and in the long run time spent in this elucidation was time saved. We must study and supply the psychic needs of the child just as much as we did his physical needs but it was surprising how dangerously little attention was paid to this. Equally the subjective aspects of illness of all kinds were inadequately studied.

* An abbreviated form of a paper which will appear in the *British Journal of Urology* for September, 1941

EAR, NOSE AND THROAT SPECIMENS IN THE ROYAL COLLEGE OF SURGEONS

ST C T writes: London possessed perhaps the largest and most valuable collection of museum specimens in existence illustrating the surgery of the ear, nose and throat. The museum of the Royal College of Surgeons received one of its earliest gifts illustrating the normal anatomy of this region from Toynbee, who presented 300 specimens of the temporal bone; these were later enriched with Arthur Cheatle's unrivalled series of sectioned temporal bones. The basis of the group of specimens related to rhinology was formed when the large collection of Onodi, from Budapest, was secured and presented by British oto-laryngologists. A valuable addition to the laryngological section of the museum was made by V E Negus, who presented the specimens on which he founded his classic study of the comparative anatomy and physiology of the larynx; these escaped damage when the museum suffered during the bombing in May last. Owing to the dispersal, for greater safety, of the specimens then undamaged it has not yet been possible to compile a complete statement of the loss suffered by the museum from enemy action, but the catalogues of the museum have been preserved and it will be possible to reproduce many specimens of normal anatomy from fresh material. The Onodi collection was heavily damaged but about 95 specimens are intact, and the others, being of normal human anatomy, can in time be replaced. The Toynbee and Cheatle collections have suffered even more severely, but it is to be hoped that after the war young aural surgeons will re-establish them. The 14 specimens of the anatomy of the paranasal sinuses recently presented by the late Professor Hajek, are intact. These formed part of the specimens which Hajek had shown, during nearly 50 years, in his famous practical classes.

ALMONERS CARRY ON

THE almoners department of the Royal Infirmary, Newcastle-on-Tyne experienced a lull in its activity at the beginning of the war. Admissions to the hospital were cut down and outpatients also became fewer owing to evacuation. A new task fell to the almoners, however, who had to arrange the transfer of convalescent patients to E M S hospitals. Outpatient attendances have gradually increased again but not to prewar level, since people are unwilling to travel far to seek advice—especially during the darker months—unless there is something urgently wrong. All convalescent homes on the north-east coast of Northumberland have been closed, the only convalescent homes for adults now available being at Ilkley in Yorkshire and Silloth in Cumberland. The Silloth home also takes children over six. Children from five to fourteen can go to the Children's Holiday Association Home at Whickham, and those between three and thirteen can go to the infirmary's own home at Greycourt Riding Mill, and to Newbrough Lodge. Children who need nursing—orthopædic cases with legs in plaster, for example, or children with chorea—can be looked after at these two homes and get complete rest. They have returned looking no and healthy, and showing a good gain in weight. convalescent home which took women and child including mothers and their babies, was in a much ru area and at last had to close; another was taken ove by the Government for other purposes.

Spa hospitals have remained open for patients wi rheumatic complaints, and the infirmary almoners hav continued to send patients to Harrogate and Buxto and to keep an eye on them when they returned to work. Acting as almoners in the original sense, they have arranged for grants from the National Society for Cance Relief to provide extra nourishment for needy patient. Of the 18 patients helped during the year, 10 died bu the grants for invalid diet did much to make their last illnesses more tolerable. Of the rest, 6 are still receiving weekly allowances and are making good progress, and 2 have been crossed off the list, as showing no further evidence of cancer. These 2, who were very poor, were treated with radium, one for three the other for ten months. They put on weight steadily, and the grant was not stopped until they were reported to have recovered from their treatment. Grants from the Soldiers, Sailors and Airmens Families Association have been administered to the wives of men in the Services. Their government allowances cover their ordinary needs, *but the grants have been* invaluabl for special expenses arising during illness—for example, to pay the cost of ambulances, of surgical appliances and of extra food. The Tyneside Council of Social Service has visited many of the infirmary patients during the year and has given grants for convalescence and to provide special treatment or appliances where these were needed. The almoners have also been able to help a girl who was crippled by arthritis to find work, and to find homes for two children whose parents were separated and whose mother was mentally unfit to look after them. These samples from the duties of an almoner give only a shadowy idea of the thought, tact and energy which go to the successful care and aftercare of even a single hospital case.

TRAUMATIC ASPHYXIA

J Grant Bonnin
M.B MELB F R C S, M R C O G
FRACTURE REGISTRAR AT THE WEST LONDON HOSPITAL

Characteristic illustrations of traumatic asphyxia show the patient cyanosed from the mid-thorax to the vertex of the skull, with bright red subconjunctival hæmorrhages and grasping an oxygen funnel and so potent is suggestion that—overlooking the normal colour of the skin visible below the discoloration and the fact that the patient shows no distress—one is convinced that were it not for this life-giving supply of gas death must inevitably ensue In fact the patient probably has no oxygen lack This is one of many confusions which have crept into the literature.

Some observers record that the skin is a patchy blue colour (with streaks of normal skin between) which fades without intermediate colour change in an average of 4 days others that there is an associated petechial rash in addition which fades in 10–14 days. A few report the appearance of intermediate colour changes during fading which suggest that the blood must be extravascular: most fail to distinguish one discoloration rom another or to record the rate and method of fading t appears that there are certainly two types of skin iscoloration one a generalised bluish-purple tint, which may be of a patchy distribution, the other a petechial rash These two skin lesions are often present together and with them may be seen bruising of the usual type. Some surgeons who have sectioned the skin find red blood-cells outside the vessels, others find dilated capillaries or normal skin

I wish to report a case with special reference to the skin changes and to suggest a theory which may explain the discrepancies in reported cases

CASE-HISTORY

A shopkeeper aged 37, was admitted to the West London Hospital at 10 50 P.M. on Dec 9, 1939, having been knocked down in the street at 10 o clock. He and his wife were about to step on to a traffic island when a car struck him in the chest and threw him to the ground He was knocked out for a minute and then picked himself up He was dazed and unsteady, and was brought by ambulance to hospital. His wife stated that he was struck by the mudguard and thrown to the ground, the car did not pass over him or press on him in any way

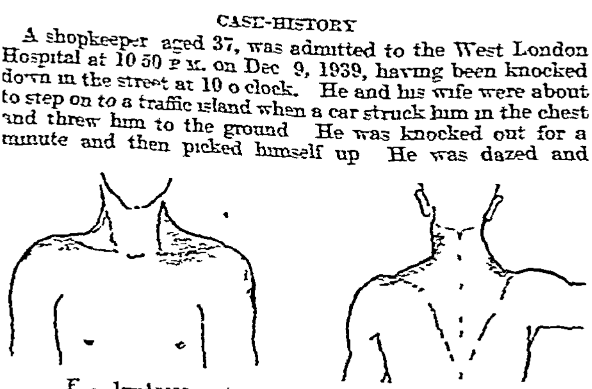

Fig 1—Areas containing petechiæ in case reported.

On admission, he was conscious and quite collected He had a faint bluish discoloration of the skin of the face and neck respirations normal pulse-rate 96, blood-pressure 120 70 mm Hg He had an abrasion over the left zygoma, and a laceration over the right which required three sutures The conjunctivæ of both eyes were scarlet the only remaining patch of normal conjunctiva being a small wedge at the upper and outer angle of the left eye There was extensive bruising around the right eye, and the nose was bleeding There was a bruise over the 5th left metatarsal and clinical examination suggested a fracture of the base of the metatarsal later confirmed by radiography, no other serious injury was detected clinically or radiographically The patient complained of pain in the left shoulder though he could move it freely There was discoloration of the skin in the areas shown in fig 1 This consisted of multiple dark petechial spots of irregular size evenly scattered and thinning towards the edges The soft palate and the posterior part of the hard palate also showed petechial spots and a few spots were noted on the under aspect of the tongue where there was one fairly large submucous hæmorrhage The ear drums were normal No petechiæ were found elsewhere His face was congested but not cyanosed

Congestion did not extend below the root of the neck, and disappeared entirely in 24 hours He had no hæmoptysis; vision and hearing were good

Progress—On Dec 10 he was comfortable Blood-pressure 128,76 Petechiæ had increased, a faint crop now being apparent from the level of the second rib on the left, extending down the arm to 1½ in below the acromion Temperature 99 2° F There was more œdema and swelling round the eyes and bruising had appeared round the left eye The conjunctivæ were chemotic and brilliantly red On Dec 11 the rash began to fade at the edges, and the skin between to assume a darker colour with a yellowish tint at the edges The chemosis subsided, though the conjunctival discoloration remained Blood-count red cells 5,700,000 white cells 9300, colour-index 0 96 Temperature 99 2° F Next day pigmentary changes of the ordinary hæmatoma were apparent in the affected skin A bluish-green discoloration united the petechial spots at the centre of the area, and faded to yellow at the edges Temperature normal From Dec. 13 onwards his condition rapidly improved The conjunctivæ remained scarlet, peri-ocular bruising rapidly subsided On Dec 14 a walking plaster was applied to the leg Next day the petechiæ in the mouth had completely gone Those on the skin were now blurred and indistinct, but the skin was coloured greenish-yellow The patient was discharged to attend as an outpatient On Dec 18 all discoloration had gone from the skin Conjunctivæ still bright red, but slowly clearing On Dec 25 the conjunctival hæmorrhage had almost gone, leaving a faint brownish yellow discoloration.

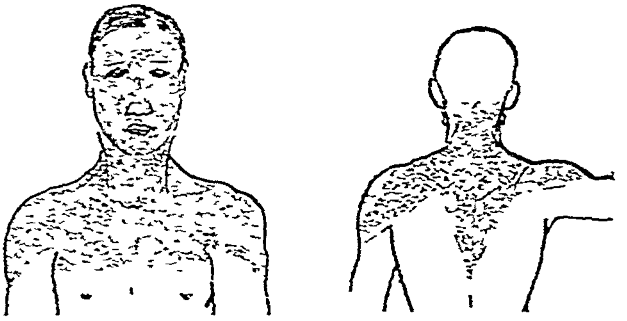

Fig 2—Areas in which petechiæ may appear in traumatic asphyxia.

DISCUSSION

The first recorded cases of traumatic asphyxia were noted by Ollivier (1837) after a panic on the Champ-de Mars in Paris The condition was recognised in Germany as Druckstauung or Stauungsblutungen, and in France as "masque ecchymotic In America Huer (1923) collated 127 cases from the literature to which a further 16 were added by Laird and Borman (1930) A further 12 cases (exclusive of Russian literature) have been recorded since Following the work of Braun (1900) Beach and Cobb (1902) removed a portion of skin for section and found no extravascular corpuscles this single observation seems to have carried undue influence in all the subsequent literature Perthes (1900) put forward a theory explaining the distribution of the discoloration on the grounds that the absence of valves in the vessels of the upper limb girdle allowed the development of back pressure He regarded the discoloration, however as due to extravasation of blood into the tissues, an idea discredited later by Braun (1904) Beach and Cobb (1902) and Winslow (1905)

TREATMENT

In all the 310 cases of enuresis the urethra was dilated with metal sounds on one or more occasions The treatment was given under a general anæsthetic which allowed me to conduct endoscopy at the same time

A firm rubber cushion was placed under the buttocks and the external genitals were inspected and cleansed In boys meatotomy was done if necessary , the calibre of the urethra was judged, the cystoscope passed, and the residual urine estimated Dilatation was then carried out In both sexes I used a special set of curved metal sounds marked in the French scale from 5 to 26 and made to my design (Willen Bros) , they are suitable for children up to the age of 14 It is not easy to pass an adult size metal sound of small calibre on a very young boy, and the attempt should not be made by anyone inexperienced in urethral instrumentation in children If a proper set of metal instruments is not available gum elastic bougies may be used, but these should first be well softened by soaking in hot water In the male treatment should always be carried out with the patient lying on his back

The cases fell into the categories indicated below Among those giving poor results were some for whom repeated treatment was advised but refused

	Per cent
Some benefit from urethral dilatation	97
Benefit from a single treatment	80
No further enuresis after a single treatment *	30
No further enuresis after 2 or more treatments *	25
Continued enuresis in spite of repeated treatments but symptoms improved	42

* Follow up covering from 3 months to 2 years

There is a striking variation in the extent to which the urethra can be dilated in children of the same age When repeated dilatations were necessary, no benefit resulted if too short an interval was allowed between the treatments , the shortest interval should be a month, and most of the repeated dilatations were carried out at intervals varying from 1 to 3 months

DISCUSSION

Inflammation figures predominantly in these cases of enuresis In some patients the enuresis developed suddenly in connexion with an attack of inflammation, generally associated with one of the exanthemata , in others enuresis merely became worse after one of these infections The fact that 84% of the cases developed before the sixth year reminds us that infections and other inflammatory diseases are common at this period of life The preponderance of girls (61%) is significant, since attacks of pyelitis (pyelonephritis) are commoner in females than males Folsom (1935) holds that pyelitis in children commonly arises as a spread of infection from the posterior urethra In many cases of acute pyelitis in women and children ,urethroscopy later reveals chronic posterior urethritis and it seems likely that the upper urinary tract infection is secondary to the lower focus, and may in the adult cases have originated in childhood

Chronic diurnal frequency of micturition was present in 77% of this series This is always an outstanding symptom in cases of inflammation of the posterior urethra and bladder neck , adults with chronic frequency in whom the urine is not heavily infected commonly have cystitis only at the neck of the bladder In diurnal enuresis the history shows that the symptom is a final expression of bladder-neck irritation which has previously shown itself as chronic frequency In nocturnal cases irritation of the posterior urethra, acting through the lower centres of the cord, results in micturition The presence of vulvitis in 57% of the girls suggests a strong relation between the inflammatory process and the enuresis, especially as the external urinary meatus was always affected Chronic cervicitis was rare, but it is important since it may have a bearing on the relationship between cervicitis and cystitis in adults

Independent observers have established the fact that in females, within and deep to the mucous membrane of the front of the trigone, the internal urinary meatus and the posterior urethra, there is a group of structures which may be true glands or epithelial rests derived from the overlying transitional epithelium, but which the microscope has shown to be commonly if not constantly inflamed Cabot and Shoemaker (1936) have failed to find these structures in the fœtus but they have identified in young children, which suggests that are acquired as a result of a local—probably inflamma-tory—stimulus In the male the gland orifices of the prostate open into the prostatic sinuses and the orifices of the ejaculatory ducts on the forepart of the verumontanum , in these localities inflammation is common. In anterior urethritis, whatever the infecting organism, all the gland orifices of the anterior urethra show evidence of infection in due course, and as a rule posterior urethritis is found later , thus the tendency to backward spread is well established, in children as well as adults In the female the vulval glands are the homologues of the anterior urethral glands in the male , and the paraurethral glands of Skene and any glands (except those of Bartholin) which open directly into the urethra are the homologues of the glands of the prostate , and an infection of the vulval glands automatically involves the urethral glands, as urethroscopy shows

Campbell (1935), in a cystoscopic study of 219 girls with persistent enuresis, found granular urethritis in 35% Spence and Moore (1939) investigated 50 girls aged 3-14 years with a history of acute pyelitis, previous pyuria, or unexplained frequency day and night with normal urine , 20 had enuresis From cysto urethroscopy they concluded that pathological urethral conditions are unexpectedly common in children and are comparable to those found in adult women Chronic granular urethritis was present in 76% of their cases, often accompanied by a reduction in calibre and a loss in elasticity of the urethra MacKenzie and Beck (1936), from histological study of 30 female urethræ obtained at autopsy, found chronic urethritis in 95%

My own observations on young adults with different degrees of stenosis of the urethra or the meatus convince me of the importance of inflammation in childhood It is a commonplace of cystoscopy and urethroscopy in adults that mild localised inflammatory foci are present at the bladder neck and in the posterior urethra, though the urine may give no evidence of infection The same findings are common in cases of enuresis in children The worst cases of construction of the external urinary meatus in boys always showed inflammation of the orifice or the mucosa within it , in many of the milder cases no meatitis was present Meatitis was only seen in circumcised children, which suggests that circumcision should only be advised after careful consideration Residual urine was present in a few of the cases , and even those with amounts of less than 1 oz sometimes had attacks of acute inflammation of both the bladder and the kidneys , these attacks usually ceased after dilatation Cases of construction of the whole length of the urethra respond particularly well to dilatation In some the urethral wall is generally fibrosed and the urethroscope shows the change to be inflammatory Variations in the calibre and capacity for dilatation of the urethra are also common in adults, and these patients too have chronic frequency and respond to dilatation

Where the bladder contains residual urine owing to a constriction at the bladder neck the reason for improvement after dilatation is obvious In the male, where the orifices of many glands open into the anterior and posterior urethra, stretching allows of improved drainage from the gland ducts The same results can be expected in the female drainage of gland ducts in the anterior urethra reduces inflammation In the posterior urethra of the female there are no glandular orifices, but inflammation here is also improved by dilatation which probably ruptures intra-epithelial cysts formed as a result of inflammation

SUMMARY

Enuresis in both sexes is commonly associated with chronic inflammatory changes in the posterior urethra and at the bladder neck

Chronic inflammatory changes in the urethra in females are often accompanied by a simple form of vulvitis In the male these changes are sometimes initiated by inflammation at the external urinary meatus

The urine is as a rule free from evidence of infection and no specific organism has been detected to explain the inflammatory changes

In many cases there are mild renal changes indicating some slight impairment of function of the kidneys a indicated by intravenous urography t is exceptional for enuresis cases not to be benefited urethral dilatation provided this treatment is carried in the proper manner

n many cases of chronic disturbances of micturition adults the history dates from childhood

TRAUMATIC ASPHYXIA

J Grant Bonnin
M B MELB, F R C S, M R C O G
FRACTURE REGISTRAR AT THE WEST LONDON HOSPITAL

CHARACTERISTIC illustrations of traumatic asphyxia ow the patient cyanosed from the mid-thorax to the ertex of the skull, with bright red subconjunctival emorrhages and grasping an oxygen funnel; and so tent is suggestion that—overlooking the normal lour of the skin visible below the discoloration and e fact that the patient shows no distress—one is connced that were it not for this life-giving supply of gas eath must inevitably ensue In fact the patient robably has no oxygen lack This is one of many nfusions which have crept into the literature.

Some observers record that the skin is a patchy blue lour (with streaks of normal skin between) which fades ithout intermediate colour change in an average of 4 ays others that there is an associated petechial rash in ddition which fades in 10–14 days A few report the ppearance of intermediate colour changes during ding which suggest that the blood must be extraascular, most fail to distinguish one discoloration om another or to record the rate and method of fading t appears that there are certainly two types of skin scoloration one a generalised bluish-purple tint hich may be of a patchy distribution the other a etechial rash These two skin lesions are often present gether and with them may be seen bruising of the usual pe Some surgeons who have sectioned the skin find ed blood-cells outside the vessels, others find dilated apillaries or normal skin

I wish to report a case with special reference to the in changes and to suggest a theory which may explain he discrepancies in reported cases

CASE-HISTORY

A shopkeeper, aged 37, was admitted to the West London Hospital at 10 50 P M on Dec. 9, 1939, having been knocked own in the street at 10 o'clock. He and his wife were about o step on to a traffic island when a car struck him in the chest nd threw him to the ground He was knocked out for a minute and then picked himself up He was dazed and nsteady, and was brought by ambulance to hospital His ife stated that he was struck by the mudguard and thrown the ground, the car did not pass over him or press on him any way

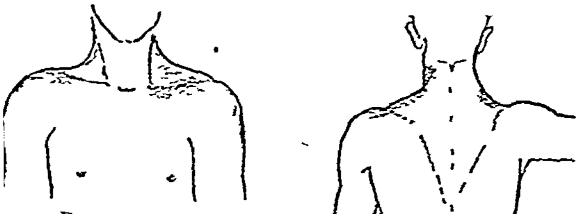

FIG 1—Areas containing petechiæ in case reported.

On admission, he was conscious and quite collected. He ad a faint bluish discoloration of the skin of the face and eck respirations normal, pulse rate 96, blood-pressure 20/70 mm Hg He had an abrasion over the left zygoma, nd a laceration over the right which required three sutures he conjunctivæ of both eyes were scarlet the only remaining atch of normal conjunctiva being a small wedge at the upper and outer angle of the left eye There was extensive bruising around the right eye, and the nose was bleeding There was a bruise over the 5th left metatarsal, and clinical examination suggested a fracture of the base of the metatarsal, later confirmed by radiography, no other serious injury was detected clinically or radiographically The patient complained of pain in the left shoulder though he could move it freely *There was discoloration of the skin in the* areas shown in fig 1 This consisted of multiple dark petechial spots of irregular size evenly scattered and thinning towards the edges The soft palate and the posterior part of the hard palate also showed petechial spots, and a few spots were noted on the under aspect of the tongue, where there was one fairly large submucous hæmorrhage The ear drums were normal No petechiæ were found elsewhere His face was congested but not cyanosed

Congestion did not extend below the root of the neck and disappeared entirely in 24 hours He had no hæmoptysis, vision and hearing were good

Progress—On Dec 10 he was comfortable Blood-pressure 128/76 Petechiæ had increased, a faint crop now being apparent from the level of the second rib on the left, extending down the arm to 1½ in below the acromion Temperature 99 2° F There was more œdema and swelling round the eyes, and bruising had appeared round the left eye The conjunctivæ were chemotic, and brilliantly red On Dec 11 the rash began to fade at the edges, and the skin between to assume a darker colour with a yellowish tint at the edges The chemosis subsided, though the conjunctival discoloration remained Blood-count red cells 5,700,000, white cells 9300, colour-index 0 96 *Temperature* 99 2° F Next day pigmentary changes of the ordinary hæmatoma were apparent in the affected skin A bluish-green discoloration united the petechial spots at the centre of the area, and faded to yellow at the edges Temperature normal From Dec 13 onwards his condition rapidly improved The conjunctivæ remained scarlet, peri-ocular bruising rapidly subsided On Dec 14 a walking plaster was applied to the leg Next day the petechiæ in the mouth had completely gone Those on the skin were now blurred and indistinct, but the skin was coloured greenish-yellow The patient was discharged to attend as an outpatient On Dec 18 all discoloration had gone from the skin Conjunctivæ still bright red, but slowly clearing On Dec 25 the conjunctival hæmorrhage had almost gone, leaving a faint brownish-yellow discoloration.

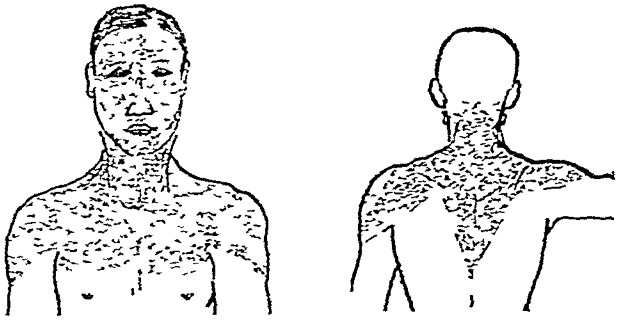

FIG 2—Areas in which petechiæ may appear in traumatic asphyxia

DISCUSSION

The first recorded cases of traumatic asphyxia were noted by *Ollivier* (1837) after a panic on the Champ-de Mars in Paris The condition was recognised in Germany as Druckstauung or Stauungsblutungen, and in France as "masque ecchymotic" In America Huer (1923) collated 127 cases from the literature to which a further 16 were added by Laird and Borman (1930) A further 12 cases (exclusive of Russian literature) have been recorded since Following the work of Braun (1900) Beach and Cobb (1902) removed a portion of skin for section and found no extravascular corpuscles; this single observation seems to have *carried* undue influence in all the subsequent literature Perthes (1900) put forward a theory explaining the distribution of the discoloration on the grounds that the absence of valves in the vessels of the upper limb girdle allowed the development of back pressure He regarded the discoloration, however as due to extravasation of blood into the tissues, an idea discredited later by Braun (1904) Beach and Cobb (1902) and Winslow (1905)

TREATMENT

In all the 310 cases of enuresis the urethra was dilated with metal sounds on one or more occasions The treatment was given under a general anæsthetic which allowed me to conduct endoscopy at the same time

A firm rubber cushion was placed under the buttocks and the external genitals were inspected and cleansed In boys meatotomy was done if necessary , the calibre of the urethra was judged, the cystoscope passed, and the residual urine estimated Dilatation was then carried out In both sexes I used a special set of curved metal sounds marked in the French scale from 5 to 26 and made to my design (Willen Bros) , they are suitable for children up to the age of 14 It is not easy to pass an adult size metal sound of small calibre on a very young boy, and the attempt should not be made by anyone inexperienced in urethral instrumentation in children If a proper set of metal instruments is not available gum elastic bougies may be used, but these should first be well softened by soaking in hot water In the male treatment should always be carried out with the patient lying on his back

The cases fell into the categories indicated below Among those giving poor results were some for whom repeated treatment was advised but refused

	Per cent
Some benefit from urethral dilatation	97
Benefit from a single treatment	80
No further enuresis after a single treatment *	30
No further enuresis after 2 or more treatments *	25
Continued enuresis in spite of repeated treatments but symptoms improved	42

* Follow up covering from 3 months to 2 years

There is a striking variation in the extent to which the urethra can be dilated in children of the same age When repeated dilatations were necessary, no benefit resulted if too short an interval was allowed between the treatments , the shortest interval should be a month, and most of the repeated dilatations were carried out at intervals varying from 1 to 3 months

DISCUSSION

Inflammation figures predominantly in these cases of enuresis In some patients the enuresis developed suddenly in connexion with an attack of inflammation, generally associated with one of the exanthemata , in others enuresis merely became worse after one of these infections The fact that 84% of the cases developed before the sixth year reminds us that infections and other inflammatory diseases are common at this period of life The preponderance of girls (61%) is significant, since attacks of pyelitis (pyelonephritis) are commoner in females than males Folsom (1935) holds that pyelitis in children commonly arises as a spread of infection from the posterior urethra In many cases of acute pyelitis in women and children ,urethroscopy later reveals chronic posterior urethritis and it seems likely that the upper urinary tract infection is secondary to the lower focus, and may in the adult cases have originated in childhood

Chronic diurnal frequency of micturition was present in 77% of this series This is always an outstanding symptom in cases of inflammation of the posterior urethra and bladder neck , adults with chronic frequency in whom the urine is not heavily infected commonly have cystitis only at the neck of the bladder In diurnal enuresis the history shows that the symptom is a final expression of bladder-neck irritation which has previously shown itself as chronic frequency In nocturnal cases irritation of the posterior urethra, acting through the lower centres of the cord, results in micturition The presence of vulvitis in 57% of the girls suggests a strong relation between the inflammatory process and the enuresis, especially as the external urinary meatus was always affected Chronic cervicitis was rare, but it is important since it may have a bearing on the relationship between cervicitis and cystitis in adults

Independent observers have established the fact that in females within and deep to the mucous membrane of the front of the trigone, the internal urinary meatus and the posterior urethra, there is a group of structures which may be true glands or epithelial rests derived from the overlying transitional epithelium, but which the microscope has shown to be commonly if not constantly inflamed Cabot and Shoemaker (1936) have failed to find these structures in the fœtus, but they have identified in young children, which suggests that are acquired as a result of a local—probably infla tory—stimulus In the male the gland orifices of the prostate open into the prostatic sinuses and the orifices of the ejaculatory ducts, on the forepart of the verumontanum , in these localities inflammation is common. In anterior urethritis, whatever the infecting organism, all the gland orifices of the anterior urethra show evidence of infection in due course, and as a rule posterior urethritis is found later , thus the tendency to backward spread is well established, in children as well as adults In the female the vulval glands are the homologues of the anterior urethral glands in the male , and the paraurethral glands of Skene and any glands (except those of Bartholin) which open directly into the urethra are the homologues of the glands of the prostate , and an infection of the vulval glands automatically involves the urethral glands, as urethroscopy shows

Campbell (1935), in a cystoscopic study of 219 girls with persistent enuresis, found granular urethritis in 35% Spence and Moore (1939) investigated 50 girls aged 3-14 years with a history of acute pyelitis, previous pyuria or unexplained frequency day and night with normal urine , 20 had enuresis From cysto urethroscopy they concluded that pathological urethral conditions are unexpectedly common in children and are comparable to those found in adult women Chronic granular urethritis was present in 76% of their cases, often accompanied by a reduction in calibre and a loss in elasticity of the urethra MacKenzie and Beck (1936), from histological study of 30 female urethræ obtained at autopsy, found chronic urethritis in 95%

My own observations on young adults with different degrees of stenosis of the urethra or the meatus convince me of the importance of inflammation in childhood It is a commonplace of cystoscopy and urethroscopy in adults that mild localised inflammatory foci are present at the bladder neck and in the posterior urethra, though the urine may give no evidence of infection The same findings are common in cases of enuresis in children The worst cases of constriction of the external urinary meatus in boys always showed inflammation of the orifice or the mucosa within it , in many of the milder cases no meatitis was present Meatitis was only seen in circumcised children, which suggests that circumcision should only be advised after careful consideration Residual urine was present in a few of the cases , and even those with amounts of less than 1 oz sometimes had attacks of acute inflammation of both the bladder and the kidneys , these attacks usually ceased after dilatation Cases of constriction of the whole length of the urethra respond particularly well to dilatation In some the urethral wall is generally fibrosed and the urethroscope shows the change to be inflammatory Variations in the calibre and capacity for dilatation of the urethra are also common in adults, and these patients too have chronic frequency and respond to dilatation

Where the bladder contains residual urine owing to a constriction at the bladder neck the reason for improvement after dilatation is obvious In the male, where the orifices of many glands open into the anterior and posterior urethra, stretching allows of improved drainage from the gland ducts The same results can be expected in the female drainage of gland ducts in the anterior urethra reduces inflammation In the posterior urethra of the female there are no glandular orifices, but inflammation here is also improved by dilatation which probably ruptures intra-epithelial cysts formed as a result of inflammation

SUMMARY

Enuresis in both sexes is commonly associated with chronic inflammatory changes in the posterior urethra and at the bladder neck

Chronic inflammatory changes in the urethra in females are often accompanied by a simple form of vulvitis In the male these changes are sometimes initiated by inflammation at the external urinary meatus

The urine is as a rule free from evidence of infection and no specific organism has been detected to explain the inflammatory changes

In many cases there are mild renal changes indicating some slight impairment of function of the kidneys as indicated by intravenous urography

The mechanism is always a thoracic crush

The distribution of the hæmorrhage coincides with that he valveless veins

Hæmorrhages have been seen in the tissues of the face neck, in the absence of local damage

Distended vessels have been found in skin sections each and Cobb 1902)

5 Rate of fading of the cyanosis is related to the length of ie the compression has lasted

6 Discoloration fails to appear under constricting bands, ggesting that if the skin is supported by an equal counter-essure, overdilatation is prevented This would also plain the absence of hæmorrhage or discoloration in the ain, where the C S.F presumably exerts a counter-pressure the vessels

7 Report of case by Kredel (1907) in which the liver of an ant 17 hours old was forcibly reduced into the abdomen m an umbilical hernia, at the end of the operation the ild's face was bluish and was marked by petechial hæmor-ages The raised intrathoracic pressure produced by the turn of the liver, together perhaps with the squeezing of ood along the inferior vena cava, produced the conditions esent in traumatic asphyxia

8 The observation of Young (1929) that in his case there as a definite concentration of petechial spots along the course f the superficial temporal veins

It would appear that back pressure dilates the vessels, nd that the anoxæmia which continues for the length f time the thorax is compressed, contributes to the aresis of the vessel walls which become overdistended nd so lose their tone The accumulation of unoxygen-ted blood in these vessels is responsible for the cyanotic ppearance, and it fades in 3–4 days as the vasomotor ontrol returns, without the intermediate colour changes een in a bruise Its rate of fading is related to the time or which the compression has lasted In a region such s the conjunctivæ, where the vessels are very lightly upported by tissue, such a wave of pressure always uptures them and produces the characteristic flame-oloured hæmorrhages These hæmorrhages, possibly rom the fact that their oxygen consumption is small, r that they can obtain some oxygen from the air, emain a bright colour for some days, and about the end f a fortnight begin to fade with the colour changes seen n other subconjunctival hæmorrhages

That long-continued low oxygen tension may result in damage to the endothelial cells lining the capillaries and capillary hæmorrhages is well known. The venous stasis produced by a paroxysm of whooping-cough, or in an epileptic seizure, may produce petechiæ, and the same mechanism may act in some cases of traumatic asphyxia If it were the usual cause one would expect that after any long-continued squeeze petechiæ would be found in addition to cyanosis This is not invariably so It appears that a further factor is involved

If the blow on the chest is sudden and violent, the sharp rise in capillary pressure may be sufficient to produce capillary hæmorrhages, and the duration of the subsequent squeeze, if any, will be of less importance The distribution of the hæmorrhages suggests that this rise of pressure is transmitted along the veins The irregular distribution of the petechial spots in some cases may be explained by the direction of the force and subsequent chest deformity, producing different waves of pressure in different veins This theory was suggested by the case reported here, in which small areas showed scattered capillary hæmorrhages, whereas cyanosis was almost non-existent Compression was of short duration, and the characteristic eye findings established the diagnosis A sudden wave of back pressure had produced petechial hæmorrhages, and the time of the compression was so short that venous tone was damaged very slightly—only temporarily shocked Only one comparable case of rapid compression has been reported, in most of the cases of slow compression there were no petechiæ In cases where a rapid onset of compression was followed by maintenance of the pressure, cyanosis and petechiæ were common Experiments have been carried out on rabbits by Perthes, but they were inconclusive The difficulty is to find an experimental animal in which valves are absent from the upper thoracic region and neck

It may be concluded that a slow squeeze produces cyanosis, a rapid squeeze is likely to produce petechiæ, and the combined type of injury produces cyanosis together with petechiæ I present this case as one of the rare examples of the rapid squeeze, thus producing petechiæ with minimal cyanosis

SUMMARY

Hæmorrhages into the skin often occur in traumatic asphyxia Two types of skin lesion are found—cyanosis, and petechial hæmorrhages—and these may coexist Petechial hæmorrhages alone have not been reported

The cyanotic coloration fades in about 4 days with no intermediate pigmentary changes The petechial hæmorrhages fade in about 12–14 days and undergo the characteristic colour changes of a bruise

The cyanosis is due to venous stasis in overdistended capillaries, temporarily paralysed as the result of continued back pressure, and to anoxæmia produced by a slow or continued squeeze of the thorax The petechial hæmorrhages are due to a sudden wave of back pressure in the veins producing capillary rupture, resulting from a sudden blow on the thorax If the sudden force on the thorax is not relaxed then the continued pressure may produce cyanosis as well

In the absence of severe associated injury, the prognosis is good, over 90% of cases recovering

There is no treatment, other than of the complications or associated injuries

PLUMP TYPE OF GRAVES'S DISEASE *

W R TROTTER, B M OXFD, M R C P, ASSISTANT TO THE MEDICAL UNIT
K C EDEN, M.S LOND, F.R C S, SURGICAL REGISTRAR
UNIVERSITY COLLEGE HOSPITAL, LONDON

PROGRESSIVE loss of weight is generally regarded as one of the characteristics of Graves's disease but the disease may be associated with a gain in weight Means [1] for instance, says that "Occasionally a patient actually gains weight while thyrotoxic," and Joll [2] that "it occasionally happens that in the earlier stages of mild cases the increased appetite and additional consumption of food may actually lead to an increase of weight" Both these authorities evidently regard such an increase of weight as infrequent, and Joll considers that it only happens in mild cases It is, however, our experience that a gain of weight is not uncommon in untreated Graves's disease, and that the cases in which it is seen are often severe and of a characteristic type This type occurs in young women who usually show such classical features of Graves's disease as exophthalmos and lid-retraction, a large pulsatile goitre and pronounced tachycardia They are plump in appearance they have often gained weight before admission to hospital, and invariably do so when rested; they often give a history of amenorrhœa, and there is clinical enlargement of the lymphatic tissues The differentiation of this type is of practical importance because the results of thyroidectomy in such cases are less satisfactory than we have come to expect in other types of Graves's disease

In 100 cases of Graves's disease (toxic diffuse goitre) under our observation at University College Hospital,

---

* These observations were made at a clinic for the study of thyroid disease set up in 1938 by the Medical and Surgical Units University College Hospital

[1] Means J H The Thyroid and its Diseases Philadelphia, 1937 p 308

[2] Joll C A Diseases of the Thyroid Gland, London, 1932, p 410

Characteristic features —Apart from the striking discoloration of the head and upper part of the thorax and the brilliant red conjunctivæ the following facts about the skin lesion are notable —

1 It is limited anteriorly by the third rib interspace, posteriorly by the triangle of skin over the trapezius, laterally it descends to the level of the insertion of the deltoid (fig 2)

2 The ears and the scalp may remain free from discoloration, or show it to a lesser extent

3 Areas of skin which have been supported by firm outside pressure at the time of the accident show little or no discoloration (such areas may be produced by the headband of a hat or the constriction of a collar)

4 The mucous membranes of the mouth, though seldom showing the general discoloration, often show petechial hæmorrhages

5 The ear drums have shown petechial hæmorrhages in a few cases

6 The subconjunctival hæmorrhage usually completely fills the visible conjunctivæ, but in milder cases may leave clear areas

7 Cases which have died from associated injuries have not been reported to show at autopsy discoloration or petechiæ in the meninges or pleura, though some subpleural hæmorrhages have been seen

8 After 24 hours, the petechial rash, if present, is found to have extended, the peripheral areas showing fainter and more scattered petechiæ

9 The characteristic skin lesions are often associated with ocal bruising and hæmorrhages into the tissues of the neck

The development of the discoloration seems to coincide with the compression In a mild case it may be almost the only sign of the condition A coloured plate of the condition in a child is to be seen in Linington's article (1915)

Associated injuries —In a third of cases consciousness is lost, usually for a short period, sometimes for hours Occasionally cortical irritation has been noted with associated convulsive movements, irritability, restlessness and disorientation Fractures of the skull have not been reported but spinal-cord and nerve injuries are sometimes seen (Ocular signs are found in 10% of cases) Associated thoracic injuries are common One or more ribs may be fractured, or the clavicle Damage to the deep thoracic structures when present is usually associated with a small hæmoptysis Pulmonary œdema has sometimes occurred, and hæmothorax has been recorded in 3 cases Injury to the abdominal organs is uncommon but when found follows the expected lines hæmo-peritoneum and ruptured intestine have been seen Not uncommonly there is moderate abdominal rigidity, possibly associated with vomiting after the accident, but this clears up rapidly

Progress —After recovery from shock, and if there are no complicating lesions, the patient makes a rapid and uninterrupted recovery In 3–4 days he feels well, and the blue discoloration has gone Discoloration from petechial hæmorrhages probably takes 12–14 days to disappear The subconjunctival hæmorrhages are slowest to subside, and faded in my case with the characteristic colour-play of a bruise at about the end of the third week Optic atrophy may be a late complication If the patient does not die immediately from associated injuries the prognosis is good, over 90% of cases recover Death at a later stage is usually due to an infective complication such as pneumonia or empyema Only the associated injuries and complications require treatment

Pathology —Huer (1923) has summarised autopsy findings in these cases Some indication of their variety can be deduced from the list of associated injuries Hæmorrhages have been noted post mortem into the tissues of the face and neck, and into the orbital tissues We are concerned here mainly with the skin findings, and these have been made on skin surgically removed from surviving subjects Sections of skin on 6 different subjects have been described No skin section was made in the case reported here because by the time I fully realised its importance the value of such sections was already lost Since, however, the play of colours seen in the skin indicates the hæmolysis of extravascular red cells, there must have been rupture of vessels with hæmorrhage into the skin Skin findings in reported cases are as follows

Beach and Cobb (1904) Normal skin

Winslow (1905) Distended capillaries No blood outside the vessels

Braun (1904) Blood present in the skin outside the capillaries (Section by Aschoff)

Bolt (1908) A number of sections showed normal skin, but a careful examination of further sections showed a few extra capillary red cells

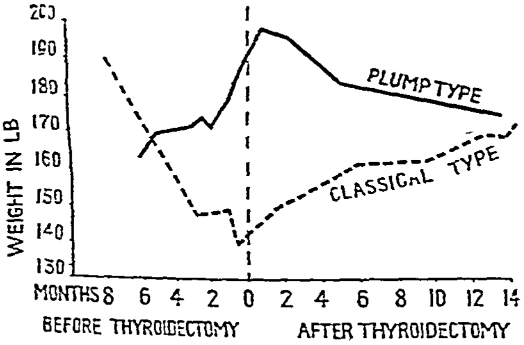
Robertson (1914) (two cases) (1) No hæmorrhage into the tissues, but "perivascular infiltration", (2) Blood pigment and hæmorrhage in the deeper layers of the skin and the subcutaneous fat

The evidence in favour of hæmorrhage occurring into the tissues in some cases may be summarised thus in 3 reported cases sections showed hæmorrhage into the skin, at some autopsies hæmorrhages were found in the tissues of the face and neck, suggesting that smaller hæmorrhages into the skin were likely, retinal hæmorrhages have sometimes been observed, in some cases, including mine, the skin discoloration fades with the colour changes of a bruise, petechiæ may be present even when such colour changes are not reported Cyanosis was accompanied by petechiæ in 14 of the reported cases So far no case has been reported showing petechiæ alone, though I believe that might be possible, in many cases, perhaps most, cyanosis occurs alone, though close examination of future cases will probably show petechiæ to be commoner than is thought The cyanosis tends to be patchy with normal skin between, and may mimic petechiæ

Ætiology —The condition has always been reported as the direct result of violent thoracic compression This has resulted from a variety of mishaps—crushes between vehicles, or between individuals in a terrorised crowd, street accidents, lift-shaft accidents and the like Less commonly it is caused by a "squeeze" (produced by the sudden failure of air pressure in a high pressure diving suit) when diving, or by the so called "jack knife" injury, in which a weight falling on the back brings the chest into forcible contact with the knees and thighs The compression may act briefly, 3–4 minutes being the most commonly recorded time, or, if less severe, for as much as 20 minutes, when the subject is pinned under a compressing weight The crush may have been rapid in onset and maintained, or may occur slowly and be released equally slowly The head and neck commonly escape injury, but the abdomen is often injured Most cases have occurred in young people, perhaps because of the greater elasticity of the chest at this time of life, and the fact that such a severe injury is likely to kill older people immediately from shock It has been recorded after epileptic fits (Alexander 1909, Coullie 1928) Hueter (1874) suggested that the cause was mechanical, the discoloration being due to back pressure in the veins, with dilatation, and that its distribution was due to disturbance of the cervical sympathetic supply to the upper limb-girdle and face The sympathetic disturbance was supposed to result in some way from the injury to the sympathetic in the abdomen While there is no doubt that the bluish discoloration is due to excessive unoxygenated blood in the dilated skin vessels, its peculiar distribution cannot be explained on Hueter's theory, nor is there any evidence of the sympathetic damage which he postulates Perthes (1900) first drew attention to the absence of valves in the veins of the head, neck and shoulder-girdle This finding fitted in with the distribution of the lesions, and has been accepted as explaining it by most writers since He supposed that compression of the thorax resulted in a regurgitation of blood back along the veins, with final rupture of the peripheral venous capillaries The only valves present in the area of veins affected—at the junction of the internal jugular, and innominate veins—he thought to be incapable of resisting an "injection mass" starting in the superior vena cava This more satisfying view of the condition held the field till Beach and Cobb cut their sections of the skin and found no hæmorrhage into the tissues, throwing discredit on the second part of Perthes' theory Subsequent writers have been in agreement or disagreement according to whether, in their own particular case, hæmorrhage was or was not found in the tissues The following points support the theory of a wave of back pressure in the veins ere described In all our cases the appetite was very large in none was there any fall of pulse-rate while the weight was increasing and in all the cases successfully operated on the weight fell steadily after operation The chart illustrates the fall of weight after thyroidectomy: and the following case demonstrates the large appetite and shows that weight can be gained without a coincident fall in metabolic rate

CASE 57—A girl of 16 while under observation in hospital gained 21 lb in 4 months During this time she was treated by sedatives alone, and was for the most part confined to bed Her food intake was estimated by the hospital dietitian at 4500–5000 calories per day, her basal calorie output remained remarkably constant at 2232–2304 calories per day (B M.R — 100–110%, calculated on the original weight) This demonstrates that her food intake was more than enough even for her very high metabolic rate and that the gain of weight was not due to any slackening of the metabolic rate

The prompt fall of weight in the plump type when thyrotoxicosis has been diminished by operation seems to indicate that the previous gain of weight depended on the existence of thyrotoxicosis It is therefore unlikely that the gain of weight was due to some chance caprice of appetite A large appetite is in fact a common feature of classical Graves s disease especially in the younger age-groups, but it is not sufficiently large to overcome the wasting tendency of the disease In the plump type the tendency to emaciation which is often so menacing a feature of classical Graves s disease, has been successfully overcome The same process may enable the patient to withstand better the other consequences of a high metabolic rate This is to some extent supported by our observation that patients of the plump type seem able to tolerate, without great discomfort levels of metabolism high enough to incapacitate patients of the classical type If this is so, cases of the plump type should stand a good chance of sustaining uninjured the thyrotoxic process over long periods and therefore of undergoing spontaneous recovery when the thyrotoxicosis eventually abates If we take into consideration this possibility of spontaneous recovery and also the unsatisfactory results of thyroidectomy, it seems reasonable to suggest that the plump type of Graves's disease is better treated medically than surgically



Weight curves in Graves's disease of plump and classical types

SUMMARY

A severe type of Graves's disease occurring in young women is characterised by a progressive increase of weight. There were 8 cases of this type in 100 cases of Graves s disease under observation

The other characteristics of this "plump type " of Graves's disease are the relative lack of complaints a history of amenorrhœa and pronounced overgrowth of the lymphoid tissues

In the 7 cases on whom partial thyroidectomy was performed there were 2 deaths and the operative results in the remainder were unsatisfactory

It is suggested that the gain in weight is an expression of the reaction of a young and vigorous organism to the thyrotoxic process, which in favourable circumstances might result in spontaneous cure

We therefore suggest that these cases should be treated medically

SIMPLE METHOD FOR ESTIMATING PROTEINS IN PLASMA OR SERUM

W. W. WALTHER M B Lond
DIRECTOR OF PATHOLOGY AT QUEEN MARY'S HOSPITAL FOR THE EAST END, STRATFORD, E

IN a previous paper[1] I concluded that plasma transfusion was the correct treatment in cases of shock where plasma loss had occurred Since then plasma and serum transfusion have become more widely used but this measure is, for the most part carried out blindly without first determining the extent of the deficiency which is to be made good As was pointed out in a recent annotation in THE LANCET (1941, 2, 194) a simple and accurate method is needed for the estimation of the plasma proteins The method I have been using for the last five years is rapid and requires no complicated apparatus Only 20 c.mm of plasma is needed for accurate analyses It is an adaptation of Wong's modification of the method of Folin and Denis described by Peters and Van Slyke[2]

Materials—Pyrex boiling tubes 170 mm × 28 mm marked by a ring at 25 c cm (J A. Jackson, Ltd City Road, London)

"Anti-bump " device consisting of 5 mm of glass tubing fused to the end of a glass rod 160 mm long

Pure, nitrogen-free sulphuric acid (B.D H.)

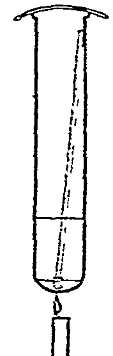
Pure nitrogen-free potassium persulphate (B D H.), saturated solution

Nessler s solution (special for blood testing, B.D.H)

Nitrogen standard Pure (Analar, B.D.H) ammonium sulphate, 0 03776 g per litre of distilled water containing 7 c cm of pure sulphuric acid It is convenient to prepare this by diluting to 1 litre 8 c cm of a 0 472% solution of the salt

Analyses may be done on heparinised plasma (using the minimum of heparin) or on serum

Method—After washing out the boiling tube with distilled water about 0 5 c cm of water collects in it. Using the hæmoglobin pipette wash out 20 c mm of serum or plasma into this water Add 0 25 c cm of pure sulphuric acid and mix Boil gently over by-pass flame of Bunsen burner with "anti-bump rod in position (see figure) When thick white fumes rise and fill the tube, cover with a watch-glass and boil for 3 min The solution is then quite black Remove the flame for 2 min and then add 0 5 c cm of saturated potassium persulphate solution Mix with anti-bump rod and replace flame Boil without watch glass until thick white fumes rise again then replace the watch glass and boil for a further 2 min after which the solution will be clear and colourless Cool dilute with distilled water to the 25 c cm mark holding the tube with the 25 c cm mark at eye level and the anti-bump rod removed Replace the rod and wash well in the solution Use any convenient volume (I use 5 c cm of the solution placed in an ordinary test-tube) and add 2 c cm of Nessler's solution A similar volume of standard solution is treated in the same way Mix by inverting twice and compare at once in the colorimeter Equal colour indicates 1000 mg of total nitrogen per 100 c cm of sample A direct reading may be obtained by fixing the unknown at "10 and moving the standard to match The reading of standard × 100 = mg of total nitrogen per 100 c cm of sample The reading is greatly facilitated by placing a spectrum blue colour filter (Ilford, Ltd) over the eyepiece Unless gross nitrogen retention is suspected a subtraction of 50 mg to cover the non-protein nitrogen gives the figure for protein nitrogen which when multiplied by 6 25/1000 gives the protein percentage The reagents should be tested occasionally by blank estimations



---

[2] Peters J P and Van Slyke D D Quantitative Clinical Chemistry vol II Methods 1932 p 527

CLINICAL FEATURES IN 8 CASES OF PLUMP TYPE OF GRAVES'S DISEASE

Case	Gain of weight	Age	Complaint	Duration	Amenorrhœa	Eye signs	Enlarged tonsils	Palpable spleen	Pulse-rate	B M R
27	4 lb in 1 month	26	Goitre, prominent eyes, gain of weight	9 months	+	Exophthalmos, lid retraction	+	0	94–104	
57	21 lb in 4 months	16	Goitre, prominent eyes	6 months	+	Ditto	+	0	100–120	+ 102% + 100
60	10 lb in 3 months	18	Diplopia	8 months	0	Exophthalmos ophthalmoplegia	+	+	100–130	+ 79% + 65
93	10 lb in 3 months	27	Goitre	5 months	0	Exophthalmos, lid retraction	+	+	112–136	+ 90 + 100
129	17 lb in 1 month	17	Amenorrhœa	3 months	+	Exophthalmos	+	0	100–110	
172	14 lb in 3 weeks	19	Goitre	4 years	0	None	+	0	100–130	+ 76% + 68%
173	29 lb in 5 months	17	Giddiness	5 months	+	Exophthalmos	+	0	104–120	+ 37% + 34%
202	44 lb in 7 months	24	Run down	11 months	+	Lid retraction	+	0	112–128	

there were 8 characteristic examples of the plump type and 8 others which had many features in common with this type The existence of transitional cases shows that the plump and classical types are variants of the same disease' not sharply demarcated from each other All 8 typical plump cases were in young women between the ages of 16 and 27 Of the remaining 92 cases nearly two-thirds were over the age of 30 and the male to female ratio was 1 4

PATHOLOGY AND CLINICAL FEATURES

In the 7 plump cases which were operated on the thyroid was found to show all the usual features of Graves's disease The glands were large and very vascular and histologically all showed epithelial hyperplasia with some lymphoid infiltration In the 2 cases which came to autopsy enlargement of the lymphoid tissues elsewhere in the body was particularly conspicuous

An outstanding feature of the plump type is the paucity of complaints in spite of the severity of the disease Often the disease is first revealed by the comments of friends on the swelling of the neck or the prominence of the eyes, or noticed by a doctor who has been consulted for some other reason Such common symptoms of Graves's disease as breathlessness and palpitations were not complained of by any of our patients and were sometimes denied on questioning Yet these cases displayed to a marked degree the common physical signs of Graves's disease, they had high pulse-rates and high metabolic rates It was therefore surprising to find them so little incapacitated by what was manifestly a severe form of the disease that all were able to remain at full work until admission to hospital

It will be seen from the table that in all but one of the cases symptoms had been noticed for less than a year Nevertheless, physical signs were invariably prominent when the patient sought medical attention, and it therefore seems that in this type of case the disease develops rapidly

Amenorrhœa was present in 5 cases, this is in contrast to its incidence in Graves's disease as a whole, for it occurred in only 4 out of the 27 other female cases under the age of 30 A period of amenorrhœa lasting for several months is sometimes the only symptom and is liable to give rise to a suspicion of pregnancy

The general state of nutrition of these patients is most fairly described by the word "plump", but occasionally they show an obviously pathological adiposity They are, however, vivacious girls, interested in their surroundings and resenting long confinement to hospital They are not unduly worried by the fear of operation

In all 8 cases the thyroid gland was diffusely enlarged, firm and pulsatile Eye signs were present in all but 1 case, exophthalmos, however, was commoner than lid-retraction, which is contrary to our experience of the usual type of Graves's disease The fine tremor of the outstretched fingers, usually regarded as typical of Graves's disease, was slight or absent, but irregular choreiform movements were present in the hands cases The skin was obviously warm and moist, the pulse-pressure raised, indicating a high degr peripheral vaso-dilatation Definite tachycardia present in all cases, but cardiac enlargement, auric fibrillation and congestive failure were not encount

The increase in lymphoid tissue which was note autopsy showed itself clinically by enlarged non-infe tonsils, palpable lymph-glands in the neck and a palp spleen Of these, enlargement of the tonsils was most constant feature, being present in all our cases contrast to an incidence of 7 out of 34 other case Graves's disease under the age of 30

TREATMENT

Subtotal thyroidectomy was performed on 7 of cases, the remaining patient being treated by X therapy In spite of adequate preoperative treatm 2 cases died within 3 hours of the operation There only 1 operative death among the other 63 cas Graves's disease operated on which suggests that plump cases are poor surgical risks The cause of 2 deaths was not apparent, but since their cond deteriorated after a brief period of respiratory embar ment these patients may be unduly susceptibl anoxæmia In this connexion, it is perhaps recalling the supposed association of unexpected d on the operating table with generalised hyperplasia o lymphoid tissues—the so-called status lymphaticus

The late results of thyroidectomy in the plump of Graves's disease were also less satisfactory th had come to expect from our experience of the clas type Tachycardia decreased relatively slowly an no case did it fall to a level of 80 beats a minute u year had elapsed after operation In 3 cases the g has recurred Our impression is that surgical treat of this type of Graves's disease is both more dang and less satisfactory than in the ordinary type of ca

One case only was treated with X rays (case There was no immediate improvement, but a year treatment the patient was decidedly better, the th had become softer, smaller and less pulsatile and pulse-rate was 86 A year later the pulse-rate is 66, and the B M R + 23% When improvement occu gradually as this, it is difficult to decide whether to be attributed to any particular form of treatme merely to the lapse of time

DISCUSSION

An increase of metabolic rate, if not compens for by an increased intake of food, must inevitably to loss of weight, and there can be little doubt th increase of metabolic rate is the immediate cause of wasting so commonly met with in Graves's dis If a patient with Graves's disease is found to gain we there can be but two explanations either the meta rate is decreasing with the amelioration of the dis or there has been an increase in the consumption of sufficient to counterbalance the increased metabol The latter seems to be the correct explanation in the were apparently hard work and poor appetite, and the long interval between breakfast and dinner These conditions were not reproduced in hospital and no attacks occurred It seems likely that an adequate diet with suitably spaced meals would prevent the onset of attacks, though the patient was not under observations long enough to confirm this The low carbohydrate low protein diet, which Conn regards as affording a more slow and steady supply of glucose to the blood in functional hyperinsulinism, was tried, but no conclusion could be drawn from the small number of blood-sugar estimations carried out

SUMMARY

Symptoms of hypoglycæmia occur in cases of renal glycosuria, and may be of two types minor feelings of faintness and weakness, due to a low fasting blood-sugar level, or more severe attacks due to a relative hyperinsulinism following rapid loss of sugar in the urine

A case is described in which the determining circumstances for the severe attacks appeared to be poor appetite, hard work and long intervals between meals, and when these conditions were absent no attacks occurred

I wish to thank Colonel F. Whalley for permission to publish this case

ICTERUS GRAVIS NEONATORUM CURED BY SPLENECTOMY

CHRISTOPHER HARDWICK,
M D CAMB, M.R.C P
MEDICAL REGISTRAR AT THE MIDDLESEX HOSPITAL

OSWALD LLOYD,
M.D LOND, F R.C S, M.R.C O G
GYNÆCOLOGICAL REGISTRAR AT THE HOSPITAL

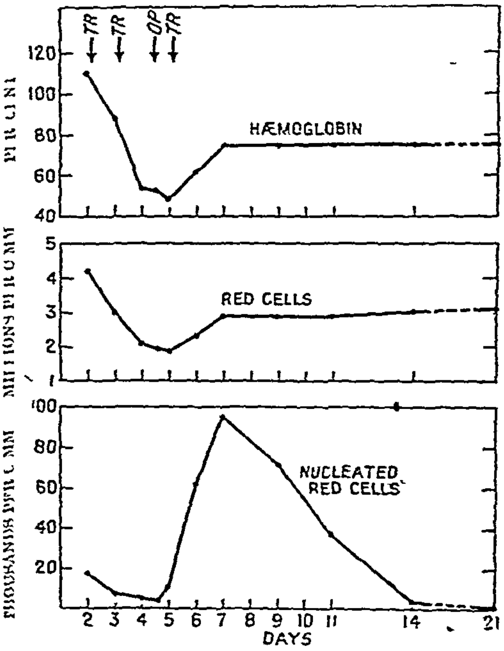
Icterus gravis neonatorum is a disease in which the outlook is always grave The mortality is high and even if recovery takes place many of the infants are mentally deficient or bear other serious stigmata In the following case removal of the spleen was brilliantly successful

CASE-HISTORY

The baby, a boy, was born at term on June 1, 1941, at 4 30 P.M The mother was a primipara and had been well during pregnancy There was no consanguinity and the father had healthy children by a previous marriage There was no family history of jaundice Delivery was by forceps owing to delay in the second stage of labour The birth-weight was 8 lb 4 oz The liquor and placenta were reported as normal

The child appeared well at birth but at 7 30 P M it was seen to be jaundiced This increased during the night and a blood-count the next day showed hæmoglobin 110 %, red cells 4,200 000, white cells 22,300 per c.mm, normoblasts 33 per 100 leucocytes, erythroblasts 51 per 100 leucocytes, total nucleated reds 17,700 per c mm A transfusion of 60 c cm maternal blood was given intravenously Examination on June 3, the third day of life showed a deeply jaundiced baby, with an enlarged liver and spleen No head retraction Blood count showed a drop in the hæmoglobin percentage and red cell count, and in the number of nucleated reds (see figure) A second transfusion of 60 c cm of group O blood was given On the morning of June 4 the child was not so well, the jaundice was intense, the scrotum was œdematous, sucking was feeble and the urine was bile stained Blood-count showed a further drop in the red cells and hæmoglobin

In consultation with Sir Alfred Webb-Johnson splenectomy was decided upon and this was performed at 7 P M on June 4 when the baby was 75 hours old General anæsthesia with gas, oxygen and ether was used and the operation was completed within 20 minutes Feeding was commenced 4 hours later and a 3 hourly regime was resumed in 24 hours Blood-counts an hour and 14 hours after operation showed that the fall in the red cells and hæmoglobin had been arrested and a reticulocyte response was beginning 60 hours after operation the nucleated red cells were 95,700 per c mm Much œdema fluid oozed from the wound, 1 c cm Kapilon was given and a further transfusion of 60 c cm of group O blood Thereafter the blood picture steadily improved and the child made satisfactory progress The spleen weighed 34 2 grammes and the histological report (R W Scarff) was "The spleen shows relative diminution of lymphoid tissue, hyperplasia of sinus reticulum with excessive phagocytosis of red cells and deposition of iron-containing pigment The sinuses contain large numbers of primitive red cells but there is little active erythropoiesis"



Blood findings TR = transfusion; OP = operation

Convalescence was prolonged by slight infection of the lower end of the wound, but the baby was discharged fit and well on July 5, fully breast fed On July 19 it weighed 9 lb

DISCUSSION

The baby showed the classical features of icterus gravis neonatorum It was severely ill, jaundice appeared early and became deep, the liver and spleen were enlarged, there was an increasing anæmia and an abnormally large number of nucleated red cells appeared in the circulating blood-stream Although spontaneous cure is well recognised, in this boy the early appearance and intensity of the jaundice made the prognosis especially grave, and by the evening of the fourth day the child had become drowsy, had refused its feeds and œdema had appeared Despite two transfusions the red cells had fallen by over two millions and the hæmoglobin by 55% The falling number of nucleated red cells suggested that the blood-forming centres were becoming exhausted Nevertheless the absence of head-retraction and convulsions encouraged the hope that if a cure was achieved the child would not have permanent cerebral damage

Dr C J C Britton of the Bland-Sutton Institute directed our attention to the possibility of performing a splenectomy The operation was first reported by Cooley (1932) in America, the child dying from peritonitis 10 days later In 1935 Cooley was able to report two successful cases but the operation does not seem to have been widely practised Despite its severity and obvious risks in one so young the operation has much to recommend it The disease has a mortality of from 50–80% (Hampson 1929, Colver 1938 McKinley 1941) and desperate measures are therefore legitimate The more orthodox treatment by repeated blood-transfusions only keeps the infant alive and tides him over until the disease process has ceased Transfusions probably have no effect on the duration of the disease and thus do not influence the ultimate prognosis Splenectomy appears to cut short the disease process and thus it may be hoped the ultimate prognosis will be correspondingly improved

In skilled hands the operation can be performed speedily, and this infant stood it well In this we were helped in that the child was mature and was a large baby weighing 8¼ lb The blood-count 4 hours after operation

If a colorimeter is not available a comparator or similar instrument can be used, but the reading of the yellow Nessler colour is greatly helped by using a blue light filter The accuracy of the method depends on individual skill in colour matching, but it is well within the limits necessary for clinical work

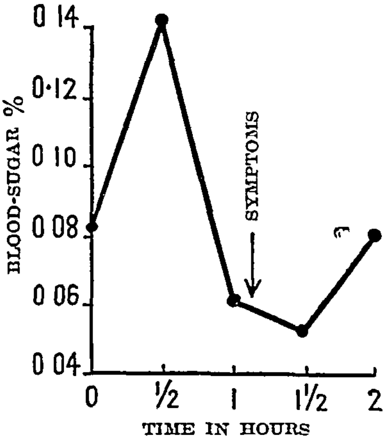
RENAL GLYCOSURIA WITH HYPOGLYCÆMIA

IAN MACPHERSON, M D Leeds, M R C P
MAJOR, R A M C , MEDICAL TUTOR IN THE UNIVERSITY OF LEEDS

RENAL glycosuria is usually considered to be a harmless condition requiring no treatment, but cases have been described in which hypoglycæmic symptoms were present It is noteworthy at present because renal glycosuria may be detected in the routine examination of recruits and the significance of the findings may be difficult to assess

A soldier of 31 suspected of pulmonary tuberculosis was sent for a specialist opinion His father had died of tuberculosis and his sister suffered from phthisis He gave a history of recurrent cough and sputum since the age of 9 when he had pneumonia and pleurisy, 3 years ago he had pneumonia, pleurisy and " heart trouble," and since then he had complained of general weakness and tiredness particularly on getting out of bed in the morning and after being at work for three or four hours, he had also fainted once or twice a month, always in the morning while at work He worked very hard in civilian life as a baker's roundsman and usually had breakfast at 5 45 A M and dinner at 12–1 30 P M He had nothing to eat between these two meals because his appetite was not good He joined the Army a week before I saw him, and since then had fainted twice on getting up in the morning

His height was 5 ft 5½ in and weight 8 st 3½ lb He was nervous, tremulous, much under weight and had a pulse-rate of 100 Sputum was small in amount and mucopurulent and a few moist sounds could be heard at the bases of both lungs X-ray examination revealed no evidence of tuberculosis and a tentative diagnosis of recurrent bronchitis and anxiety state was made, but on examination of the urine, sugar was found in moderate amount and he was admitted for investigation



Blood sugar curve after 50 g of glucose

Urine —Approximately 20 g of sugar was passed in the urine in 24 hours on ordinary hospital diet No albumin or acetone found during his stay in hospital, no frequency or polyuria

Glucose tolerance test —50 g of glucose was administered after overnight fast, the patient being on ordinary hospital diet The blood-sugar had risen from a resting level of 0 08 g per 100 c cm to 0 14 at the end of half an hour (see figure), at the end of an hour it had fallen to 0 06 and the patient complained of a sinking feeling and fainted He appeared very ill with cold clammy skin, pallor and rapid weak pulse Recovery took place in 5–10 minutes without treatment This attack of induced hypoglycæmia seemed to him similar to the spontaneous attacks he had experienced previously The blood sugar sank still further, reaching 0 052 at the next examination but returning to resting level (0 08) 2 hours after the administration of the glucose

X ray of skull no change in sella turcica

Urea clearance test 40% above average normal No hepatic function tests were carried out

He was treated on various diets (meals being served in each case at 7 A M, 12 noon 4 P M and 7 P M) with the following results

1 *Ordinary hospital diet* he complained occasionally minor fainting feelings in the morning but was otherwise

2 *Ordinary hospital diet with glucose* 15 g t d s bef *meals* no symptoms but treatment was discontinued because of severe polyuria and frequency after taking the glucose

3 *High carbohydrate low protein diet* no symptoms Specimen blood sugars taken at noon, 1 P M and 2 P M were 0 112, 0 137 and 0 143%

4 *High protein low carbohydrate diet* he felt less energetic and faintness was more pronounced but he had no attacks Specimen blood sugars taken at noon, 1 P M and 2 P M were 0 08, 0 156 and 0 106%

He was discharged much improved in general health on ordinary hospital diet

DISCUSSION

Cammidge (1930) described 200 cases of hypoglycæmia, some symptomless and many with only minor symptoms In no less than 53% sugar was present in the urine, in most cases as dextrose, indicating abnormal permeability of the kidneys for this sugar Wauchope (1933) stated that most patients with a low renal threshold for glucose experience only slight symptoms or none at all, but on several occasions symptoms have been provoked by the glucose-tolerance test, blood-sugar falling below the original fasting level towards the end of the test More recently Conn (1940), discussing the ætiology and treatment of spontaneous hypoglycæmia, gave renal glycosuria as a less common cause, he regarded it as a fasting hypoglycæmia with the blood-sugar likely to be at its lowest level after the overnight fast He said that hypoglycæmic convulsions were rare, and that a diet high in carbohydrate is usually sufficient to control the hypoglycæmia It seems from these papers that minor symptoms of hypoglycæmia in renal glycosuria are not uncommon but that severe hypoglycæmic attacks rarely occur except after the administration of glucose, as in the glucose-tolerance test Gibson and Larimer (1924) described a case in which symptoms of hypoglycæmia and a low blood-sugar were induced by a double blood-sugar-curve test, the fall in blood sugar being much greater after the administration of a second 50 g of glucose The patient in this case had experienced spontaneous attacks similar to those induced by the test but could not associate them with any definite circumstance

In the case reported here the patient complained of minor feelings of faintness on rising and occasional severe attacks similar to those occurring in the glucose-tolerance tests The faintness on rising can be accounted for by the low fasting blood-sugar level and it is suggested that the mechanism of production of the severe attacks is the same as in those following the administration of glucose Theoretically hypoglycæmia may arise in two ways, either from an inadequate supply of sugar to the blood by the liver or from too rapid removal of sugar from the circulation In my case there was no clinical evidence of hepatic deficiency and the glucose-tolerance curve was not of the high plateau type curve (similar to that seen in diabetes mellitus but with a low fasting level) which Conn associates with hypoglycæmia of hepatic origin The fall in blood-sugar must therefore be explained by the too rapid removal of sugar from the circulation

Conn suggests that in functional hyperinsulinism a rapid rise of blood-sugar, associated with the ingestion of easily absorbed carbohydrate, may overstimulate insulogenesis, and that this produces a secondary abrupt fall of the blood-sugar to a hypoglycæmic level In renal glycosuria a normal insulin response with a simultaneous rapid loss of sugar in the urine may produce the same effect, and it seems likely that the severe spontaneous and induced attacks in my case were produced in this way This is borne out by the clinical findings which were similar to those described by Conn in functional hyperinsulinism, where the fasting blood sugar is usually normal and symptoms characteristically appear three or four hours after meals and are relieved by food The attacks only last 5–15 minutes and always disappear spontaneously even though no food is taken The glucose-tolerance curve in my case was also similar to that of functional hyperinsulinism The conditions which determined the onset of his spontaneous attacks

IDEAL FOR WHAT?

"Workpeople must recognise that the conditions of industry ring war cannot in the nature of things be ideal, "
1st report from the Select Committee on National Expendi-re,[1] Session 1940–41)

This exhortation comes near the end of a report con-ining a long series of admirable recommendations esigned to improve output in war factories It minds one of the ' Don t you know there's a war n ? " used in defence of errors and omissions which o *not* arise out of a state of war Of course we must ll expect fewer of the amenities we enjoyed in the ays of peace when oranges and bananas made gay plashes of colour in the shops when petrol flowed ike water and trains ran to time But there is a *chadenfreude* which uses the war to make our lives arder than they need be It would be invidious to atalogue our grievances, because each has his own pecial ones, as well as his list like RUPERT BROOKE S, f the things he has loved Mature people would be urprised and even disappointed if they found them-elves living in Utopia and certainly factory workers o not expect the conditions under which they work even in peace-time to be ideal What they have a ight to expect is that their work shall be reasonably afe, healthy and well paid, that it shall be within he limits of their varying mental and physical capa-ities, and that they shall not be pressed to the point where the job becomes flat, stale and unprofitable

It is difficult to define more exactly what is meant by ideal factory conditions In the light of over 100 years' experience it took some 150 long sections of the Factories Act 1937 to outline them, and in the opinion of many people the 1937 Act put the minimum too low In any case it was passed too soon before the advent of war for its full effects to have been felt Yet on the whole factory conditions are better now than they have ever been and they will be better still for Mr BEVIN S drive to extend the medical, nursing and welfare services in factories and his intention to make hot meals available to the whole industrial army The new regulations require stand-ards of lighting well within the power of the average employer to provide the more enlightened had done so without legal stimulus But amenities do not make tired workers efficient, men are still working oo long hours, and some are working seven days a week, partly to meet the demands of Service depart-ments, partly because by so doing they can earn more money Overwork however, is never ideal in any ense, it is false economy both in health and output We shall never convince the so-called practical men of this except by putting into practice the findings of the Industrial Health Research Board and letting hem observe the results Fortunately for all of us here is legal control over the hours of work for women and young people The blackout too has worsened the ventilation of factories at night, wall ans and light-trap ventilators can ill replace the open door and window The select committee has its own way of screwing up production The workpeople should have their day of rest in seven but the factories should keep at it all the time Piece-rates require adjustment so as not to discourage improvement in the rate of output Managements are urged to take their workpeople more closely into their confidence All large firms should have a central personnel depart-ment and take advantage of the training courses for personnel managers and welfare supervisors organised by the Ministry of Labour Charge hands and foremen should be chosen for their qualities of leader-ship and organising ability as well as for their tech-nical skill The three days suspension without pay should be extended to cover slackness but the report recognises that the workers of this country are not to be treated as machines or as driven cattle, but as intelligent coöperators in a crusade The committee had evidence that idling is often due to bad manage-ment or lack of supervision, good management tends to reduce absenteeism Moreover lack of work and enforced idleness induce a sense of frustration which ultimately lowers morale

Much thought has been given to the removal of unnecessary hardships outside the factory People engaged on essential work should have priority passes on the transport services, while employers and work-people in neighbouring factories should be asked to relieve pressure on transport by staggering hours Fares in excess of 3*s* a week should be requited to workpeople at any establishment engaged in Govern-ment work Collaboration between the appropriate ministries should ensure that population movements are accompanied by corresponding diversions of food-supplies On less tangible issues, means should be taken to convince workers of the need for ever greater output of munitions and to help them realise the importance of their work At the same time the prevalent misconceptions about income-tax should be removed and it should be made crystal clear how the excess profits tax has snuffed out profiteering If accepted these recommendations would go far towards removing both physical and psychological inhibitions to the output of war material

THE GENESIS OF GALL-STONES

A REMARKABLE study of the ætiology of gall-stones has lately been made by MARTENSSON[1] of the Caroline Institute, Stockholm It proceeds from two primary observations, first that certain bacillus-like structures are visible in the organic stroma of cholesterol-rich gall-stones after extraction of the cholesterol and other lipoids with alcohol and alcohol-ether, and second that similar ' bacilli ' were seen, surrounded by areas of proteolytic necrosis, in the mucosa of two surgically removed gall-bladders which contained very small and apparently recently formed gall-stones The occur-rence and significance of these bacilli was systematic-ally investigated Gall-stones, obtained at operation or at autopsy, were washed in sterile saline and split open with aseptic precautions Their nuclei were scraped out, and nuclei and perinuclear layers separ-ately ground in mortars The ground material was transferred to various culture media, solid and liquid, and incubated aerobically and anaerobically for 2–6 weeks A variety of organisms grew, but attention was focused on a bacillus which resembled the struc-tures seen in the gall-stone stroma and in gall-bladder

[1] Martensson K *Acta chir scand* 1941 84 Suppl 62

showed that the hæmolytic process had ceased and the usual reticulocyte response to splenectomy was already beginning, after 60 hours the reticulocytes reached 95,700 per c mm A transfusion was given the day after operation because it was thought important to restore the blood-count more nearly to a normal level as soon as possible, so that the child would be in the best possible position to combat any infection that might develop The subsequent rise to a normal figure without any further treatment was noteworthy

The operation was performed by Sir Alfred Webb-Johnson when the child was 75 hours old and was performed as a last resort In view of its success it is probable that we should recommend operation much earlier in future As Cooley has shown, there is a danger in waiting, however well they may seem these patients are always liable to sudden death owing to failure of the respiratory centre, and he reports a case which died suddenly the night before operation was to take place We suggest that operation should be done 24–48 hours after birth, this would give time for the child to recover from its birth and would allow a complete hæmatological examination to be made and arrangements for transfusion to be completed When last seen, at the age of 15 weeks, the child was in good condition it weighed 14¼ lb and showed no signs of any unto sequelæ

SUMMARY

In a male baby with typical icterus gravis neonat the early appearance and severity of the jaundice n the prognosis especially grave In spite of two bl transfusions the number of red cells and hæmogl percentage fell rapidly

Splenectomy was performed when the baby 75 hours old and was strikingly successful The l was discharged from hospital a month later quite

This treatment seems to cut short the disease, offers a hope that both the immediate and rer prognosis of the malady will be considerably improv

Thanks are due to Sir Alfred Webb Johnson and L Carnac Rivett for permission to report this case an Prof J McIntosh and the staff of the Bland Sutton Insti for the hæmatological and histological investigations

Reviews of Books

The Life of Sir William Osler

HARVEY CUSHING London Humphrey Milford, Oxford University Press Pp 1417 21*s*

Harvey Cushing's life of William Osler was published sixteen years ago in two volumes with a number of illustrations The present edition in one volume is unaltered as to the text, which stands exactly as Cushing wrote it, but has been reproduced with only a quarter of the illustrations, so that it has been possible to present it to the reader at a price considerably lower than that of the first edition—a price, indeed, which will put it within the limits of the purse of the medical student This has been the aim of the editors Dr J F Fulton and Dr W W Francis who in their foreword dedicate the volume to the medical students for whom Osler planned and worked throughout his life

The merit of Cushing's "Life" has been thoroughly appraised and it long ago took its place among the great biographies of our time He had a great theme and handled it greatly The generation to whom Osler was personally known is almost past, and to the present generation his name is rapidly becoming a tradition but the work which he did lives, and it will be well if students of this and succeeding times learn at first hand what manner of man was he who revolutionised the teaching of medicine in his own western hemisphere, and left deep marks on that of England and Europe

Unlike many of the great physicians of the past Osler did not personally contribute any striking discovery to the science of medicine His pre-eminent service to medicine was that by his ideals and his example he infused a new spirit into the whole body of the English-speaking teachers of medical knowledge It is scarcely an exaggeration to say that until his time the education for the profession had become a stereotyped course of training for a business career, in which the majority of the teachers were content to impart their knowledge to the student with but little reference to the ideals of science and with an experience of the world of medicine outside their own country generally extremely limited Osler had prepared himself by years of work in England and Germany as well as in Canada, and when rather unusually late in his career, though still young in years, he entered upon clinical teaching at the bedside he was personally acquainted with a large number of the most active and inspiring scientific men of Canada, the United States, England and Germany, and in many instances had actually worked with them in their laboratories and hospitals Hence it was that he was able in Montreal and then in Philadelphia, but above all in Baltimore, to bring to his work the ideals and methods of the leaders of medical and scientific thought of his time His technical equipment was thus much in advance of that of the general mass of teachers, but it might have been largely wasted in another man not blessed with Osl supreme gift of friendship with his fellows, and capacity for tactful leadership Few men can have l so many devoted friends, and few are capable of retain that devotion throughout the changes of life Os was everybody's friend from the moment of meeti and neither he nor anyone whom he once met ever forg one another even after years of separation His memo for his friends and acquaintances was extraordinary, a he never lost an opportunity of renewing the bon generally by flying visits in person—moments snatcl from a busy day to forge the chain anew He was a voluminous correspondent as a rule, though when did write few could contrive a better or more satisfy letter Another characteristic served to enhance value of his teaching his medical writing was alw clear, always pointed, and often in single phrases turesque, and his numerous papers and addresses v crammed with allusions to the great writers of the p They are readily appreciated even in print, t quality was increased by an attractive delivery and a and humour which completely held his audience these attributes of a great teacher were comparati insignificant, his personality gave him his influence his fellow-travellers in this world No-one ever sp half an hour in his company without feeling him both in mind and body, a better man than he had posed himself to be He had the faculty of bring the best to the surface, largely because he gave freely best of himself—his knowledge, his experience, his id and his love of humankind without the sm reserve

Harvey Cushing wrote Osler's life from an intin acquaintance of many years, and succeeded, so far possible, in transmitting something of the charm of beloved teacher It has been a wise thought that made the work procurable to a wider public than c be reached by the original volumes

Methods of Treatment

(7th ed) LOGAN CLENDENING, M D, and EDWAR HASHINGER, M D London Henry Kimpton Pp 50*s*

ALL methods of treatment which a practitioner ma called on to advise or to use himself are described in first half of this comprehensive treatise from Kansas critical assessment of the indications and usefulnes these methods follows For the more specialised meth such as radiotherapy or anæsthesia, collaborators l been engaged but the whole is strikingly individual forthright and is leavened with shrewd wit and com sense No respect is paid to ephemeral, fashionable, pseudo-scientific treatment and omissions are as valu to the work as the emphasis laid on the simple orthodox methods New advances have been in porated in this new edition, and the whole has l revised nost important Physical training they visualise apable of building a bridge between contempla- and action, and through it almost every man woman can, they say, be developed to a level of iomic maturity Physical efficiency in their gment dictates largely the rate of industrial and cultural production, and is one of the primary erminants of military preparedness

But what is physical efficiency and how is it to be ured ? Jokl and his colleagues seek for quantitae information, as the instrument of precision dended in measurement they accept physical performce as the analogue of the divided circle in astronomy, e balance in chemistry, the thermometer in physics ius physiological, postural and anthropometric sts were correlated with athletic performances and e results are described as truly remarkable, these ibstandard youths being transformed into normal oung men On the medical side, ample evidence was orthcoming from improvement in height, weight, eneral physique and athletic capacity, employment ind subsequent career afforded evidence of full economic rehabilitation One can understand and sympathise with the enthusiasm of the leit motif Yet clearly it is difficult, even impossible, to assess the part played by the physical training itself For the ecruits were domiciled in a camp where for the first time in their lives they were subjected to discipline “ We are convinced,” say the authors, “ that most of them would have abandoned the training, which they found very strenuous, if it had not been possible to keep them under military rule Since an astoundingly large number of individuals will not seek, out of their own initiative, ways and means to develop and educate hemselves to the optimum of their potential abilities, t is necessary to introduce some system of compulsion under which the state would take charge of young citizens who are for any reason unable or unwilling to carry their weight in the economic life of the community ” They lived in well-kept tents and barracks, received a well-balanced diet, had to follow a carefully constructed time-table with ample opportunity for recreation How can one isolate any one factor in a properly coordinated regime which contrasts so strikingly with the conditions from which these recruits were salvaged, a life unsatisfactory in all ts details—bad hygiene, malnutrition, constant appreension of or resignation to a hopeless future with omplete lack of stimulation, not to mention undesirible habits and vice ? Even then the psychological ispect of physical training has to be considered—pride in achievement as well as the discipline with its epercussions which regular exercise exacts No-one wants to belittle the value of actual training in the egime, but it is right to consider the whole picture, specially since our own national physical-training novement of three or four years ago was obstructed by the claims of enthusiasts who advocated this, that or the other ‘ system ” as if it were the only factor of importance

Jokl and Cluver[4] have also studied the growth of physical efficiency in young people between the ages of 5 and 20, based on over 20,000 individual tests—in extensive survey on the principle that physical fficiency determines to a considerable extent the legree of “ fitness ” as it is understood under conditions of everyday life These tests, which were performed on English, Afrikander, Jewish, Bantu, Cape Coloured, Indian, and Chinese, comprised sprinting 100 yards, running 600 yards and putting the ten-pound shot, events selected to ascertain in exact terms the three basic principles of labour—skill, endurance and strength The results showed, first, the similarity of standards of physical performance found in the different racial groups, and secondly, the difference demonstrable between “ rich and poor ” children after puberty From the first, one is entitled to assume the basic equality of man , from the second it may be concluded that, while subnutrition (unless to the degree of true clinical deficiency) leads to no appreciable physical incapacity in the pre-puberal stage, its malevolent influence is very evident when the powerful additional strain of puberty is imposed They also quote the case-histories of athletes to demonstrate the fallacy of many generally accepted clinical concepts of the relationship between disease and physical efficiency They tell us of a champion swimmer with dementia paralytica, a first-class ski-runner with an artificial leg, a gymnastic instructor with myasthenia gravis who maintained her professional capacity with the aid of prostigmine, a first-class shot-putter with a congenital defect of the right pectoralis major , and perhaps most striking of all a very successful Marathon runner with aortic regurgitation and mitral stenosis Moreover, with L Melzer, Jokl[5] reports the results of 67 autopsies in all of which pre-existing lesions of the cardiovascular system were discovered, serious lesions which had nevertheless been consistent with outstanding athletic success These researches support the opinion often reiterated by Sir Adolphe Abrahams that physical development and athletic efficiency are basically dissociated phenomena and that a deficiency in physical development can be compensated by a high standard of functional efficiency Abrahams has maintained that given a healthy myocardium and coronary circulation no harm to the cardiovascular system can result from the greatest exertion of which a human being is capable, and he regards hyperpyrexia as the only potential danger in violent exercise under extremely unfavourable climatic conditions Even this solitary danger is not accepted by Jokl who, in his considerable experience, has not encountered an example

[4] *J Amer med Ass* 1941, 116, 2383

[5] *S Afr J med Sci* 1940 5, 4

Dr W M Frazer in his 1940 school report tells us that during the year Liverpool started an enuresis clinic for children about to be evacuated In the 269 children explored at this clinic only 4% were found with some physical condition which might account for their enuresis, and 6% had subnormal mentality The aural clinic dealt with 1080 cases of which 409 were cured, 55 referred to hospitals and 355 failed to complete treatment Of 336 cases of suppurating otitis media 173 were cured, but of 231 cases of chronic suppurating otitis media only 31 were cured We are reaching agreement that the distinction between acute and chronic suppurative otitis media is not one of time but of bacteriology Cases are acute so long as only throat organisms are present, and the chronic stage begins if there is an invasion of skin organisms from the meatus The distinction is important in treatment and prognosis, for so long as there is no invasion of the middle ear by skin parasites cure can always be obtained, generally speedily If the skin parasites settle in the middle ear cure is always tedious and may be impossible This rules out syringing for discharging ears mucosæ in the initial observations. It was a gram-positive motile spore-bearing rod. It was found in 30 cases out of 75, and in 20 of these was unaccompanied by other organisms. Cultures of the corresponding bile were made at the same time and yielded the same organism in 15 of the 30 cases in which it was present in the stones, but in no case in which it was not found in the stones. *Bacillus coli*, on the other hand, though occurring almost as frequently, was found 1½ times as often in the bile as in the calculi, which suggested that it had invaded the stones from the bile; the other organisms found were also more frequent in bile than in stones. Furthermore, colon bacilli and various cocci included among the other organisms were found not only in bile from stone-containing bladders but also in the contents of many gall-bladders containing no stones, whereas in a series of 34 such stone-free specimens of bile the peculiar spore-bearing bacillus was consistently absent. At this stage the evidence that this bacillus had a specific relation to gall-stones appeared fairly strong, and was further supported by the intimate relationship of the bacilli with stony particles in thin sections of stones when examined by agar microscopy; colon bacilli and cocci were also seen in these sections, but appeared to lie rather in the spaces between the stony particles. However, since detailed bacteriological examination of the organism showed it to be closely allied to, though not identical with *Bacillus subtilis*, the possibility of its arising in some way as a contaminant had to be excluded. This was done by subjecting 50 sterile dried lumps of agar to the same treatment as the gall-stones; contaminants appeared in only 3 instances, and none of them was the organism in question.

The next step was an attempt to induce gall-stone formation in animals by injection of cultures of the organism into their gall-bladders. Many such attempts have been made with various other organisms but never with convincing success. The rabbit was chiefly used because it does not naturally develop gall-stones. Out of 73 rabbits whose gall-bladders were inoculated with pure cultures of the organism 55 were found at autopsy to have concretions. Tiny ones were found, surprisingly enough, 24 hours after the inoculation, larger ones after intervals of weeks or months. The structure of the older ones resembled that of human gall-stones, and from most of them the subtilis-like organism was recovered in culture. Control experiments with injections of sterile saline, and of killed cultures of the organism, yielded no gall-stones, nor did others in which *B. coli* and one or two other organisms were used. The spore-bearer under investigation, however, appeared to produce gall-stones in 3 out of 4 sheep, 1 cow, and 1 pig, but not in 4 dogs. In further experiments it was injected intravenously into 8 rabbits; one of them killed at 25 days showed a proteolytic desquamative process in its gall-bladder wall but no stones; about half the others, after several months, showed gall-stones at different stages of development. Even administration of the bacillus to rabbits by mouth was followed by stone-formation in a proportion of cases. Finally 10 rabbits were immunised against the organism by repeated injection of a centrifuged bacillary emulsion, proved to contain no living bacilli; subsequent inoculation of living cultures into their gall-bladders produced neither stones nor changes in the mu the end of 5 months, although in 3 of them the o was recovered and cultured from the bile. MART tentatively suggests that stone formation may d in some way on the activity of the specific an He therefore traces the origin of many human stones to the entrance of his subtilis like organism the biliary tract, possibly from the gut, since it o in fæces. It attacks the gall-bladder mucosa, ducing a local subepithelial cell necrosis with desquamation. It tends to precipitate choles from pure bile, and the gall-stone arises from preci tion of cholesterol and bile pigment on an org stroma composed of epithelial cells and a felt worl bacilli. The stone grows and its permeable s may become invaded by other organisms present the bile, but the original organism, or at least spores, remain viable within it. Cholecystitis in ordinary clinical sense is a complication, not a cause gall-stones. The stone-producing organism is antig and if it turns out as seems possible that its antige concerned in stone formation there is clearly a prosp that the antigen may be effective in "immunisin human subjects against the development of stor

MARTENSSON'S work seems on the whole so caref comprehensive and well controlled that it shou command attention and early repetition. Yet it surprising that his organism, since it grows on standa media, has not been demonstrated by earlier worke and it is noteworthy that OLIN'S[2] search for it another laboratory in another town succeeded o 3 times out of 41. OLIN produced early stone form tions in rabbits' gall-bladders by injecting the bacil much less often than MARTENSSON did, and he sugge that MARTENSSON may have used too low a temperat in sterilising his bacteriological implements. T report from Stockholm remains therefore under t heading "not yet confirmed," pleasant as it is think that the stout lady makes her gall stones the same technique as an oyster makes pearls.

PHYSICAL TRAINING AND PHYSICAL EFFICIENCY

FIVE years ago, out of a total European populati in South Africa of a little less than two millio 119,000 were unemployed and by implicati unemployable. Among the various causes for t calamity, the low state of physical fitness was evident that a special course of training was est lished to combat the deteriorating influence unemployment and provide discipline and train for unemployed youths between 17 and 22. Th educational qualifications were so poor that th were unsuitable for anything but manual labou circumstance which combined with their defect physique excluded them altogether from labour market. Between 1933 and 1939, 14, of them were attested to Special Service Battal courses. Of these, nearly 11,000 completed training course and 9400 were subsequently placed employment. This highly satisfactory result been achieved by a combination of measures of wh JOKL and his colleagues[3] regard physical training of jaundice after birth appears to be as follows: intramuscular blood at once and repeat in a few s, if the condition fails to respond (as shown by oglobin estimations if full blood investigation is ossible) make arrangements for intravenous transfu- of matched blood (itself a by no means easy pro- ure), if the downward progress continues splenectomy rs a reasonable chance of cure

[3] Training and Efficiency: an Experiment in Physical Economic Rehabilitation. By E. Jokl, E. H. Cluver, Goedvolk, and T. W. De Jongh. Johannesburg: S African Institute for Medical Research. 1941.

WHEN DOG EATS DOG

It has been known for a long time that some micro- ganisms produce substances antagonistic towards thogenic bacteria but until lately few attempts have en made to isolate these substances and study their logical and chemical properties Dubos[1] isolated m the soil a gram-positive, spore-forming organism, er identified with *Bacillus brevis,* which produces werful bactericidal agents Originally it was believed at the bactericidal agent isolated from culture filtrates crystalline form represented a single, homogeneous mpound which was termed gramicidin, but later it was und to consist of two bactericidal substances which re both obtained in crystalline state—gramicidin, pecially effective against gram-positive organisms, and rocidine, acting against gram-negative organisms as ell In vivo, gramicidin was shown to protect mice ainst pneumococcal infections and against infections ith group A and group C streptococci under certain con- tions which did not differ essentially from the in-vitro nditions in which the substance had been shown to be actericidal Given by the intravenous route gramicidin almost completely inactive against systemic infections[2] is highly toxic to animals Tyrocidin is ineffective ainst bacterial infections in vivo, it is hæmolytic[2] ubos and Hotchkiss found that a number of soil organ- ms produced substances similar to or identical with ramicidin and tyrocidin Nothing is known yet about e chemical structure of these J C Hoogerheide[3] des- ibed a crystalline antibacterial substance isolated from soil organism, which according to its chemical and bio- gical properties seems to be identical with gramicidin, is now being tried out clinically in Philadelphia under he name H1, only local application is so far practicable ecause of its toxicity but results are favourable Also rom the soil, Waksmann and Woodruff[4] isolated a hromogenic actinomyces (*Actinomyces antibioticus*) from hich they obtained two antibacterial substances, ctinomycin A and B Actinomycin A is bright red, nhibits the growth *of many bacteria in great dilution,* ut is very toxic to laboratory animals It is mainly acteriostatic, whereas actinomycin B, which is colour- ess, is bactericidal The chemical nature of these ubstances also has not been established

The nature of the antibacterial substances, produced y *Pseudomonas pyocyanea*, known for forty years since he work of Emmerich and Loeb[5] as "pyocyanase" has een reinvestigated by Schoental[6] She confirmed the actericidal action of these substances on *Vibrio holeræ, Staphylococcus aureus* and many other organ- sms and showed that it was due to at least three frac- ions, the blue pigment pyocyanine, its breakdown pro- uct α oxyphenazine, and a third colourless, chloroform- oluble principle, most easily extractable from old culture luids This last substance is bacteriolytic towards V *choleræ*, thick suspensions of which are converted nto a gel In contrast to the original assumption of Emmerich and Loeb none of the antibacterial substances roduced by *Ps pyocyanea* are enzymes, therefore the term pyocyanase does not seem to be justified for any of them A good deal is known about the chemical nature of pyocyanine and α-oxyphenazine their antibacterial action is probably much the same as that of other bactericidal dyes of similar chemical constitution The chemical nature of the chloroform-soluble colourless bacteriolytic substance remains to be investigated The antibacterial substances from actinomyces strains isolated by Waksmann and Woodruff differ from another antibacterial agent obtained from actinomyces strains, actinomycetin, which forms the subject of many papers by Gratia and others[7] This substance, which acts against a number of gram-positive and gram-negative bacteria, and lyses a number of them is a protein and belongs most probably to the class of bacteriolytic enzymes of the lysozyme type

Now Chain, Florey[8] and their colleagues have investigated the possibilities of penicillin, isolated from the mould *Penicillium notatum* In the state of purity used in their biological and therapeutic experiments it is a yellow substance, easily soluble in water It is not bactericidal, but even when very dilute (1 2,000 000) it inhibits the growth of many pathogenic organisms, such as *Staph aureus, Streptococcus pyogenes,* meningococcus, gonococcus, *Clostridium welchii, B anthracis* and others It differs from all the other antibacterial substances isolated from micro-organisms and, indeed from most antiseptics known, by its very low toxicity Laboratory animals infected with *Cl septique, Staph aureus* and *Strep pyogenes* were cured and the results of a number of clinical trials are promising Here again we have yet to learn its chemical composition

PSYCHIATRY IN THE SWISS ARMY

THANKS to the work of Forel Bleuler and Jung psychiatry is more advanced in Switzerland than in most European countries Its importance in practical medicine is well recognised and psychiatric principles have penetrated into law, education and other fields of public life Their application to military medicine is illustrated in three recent articles[9] Though the country is not at war, the army is in a state of constant full mobilisation—very different from the transient service of a few months each year which is customary in peace-time Mental and psychological cases are common amounting—so Dr R Brun estimates in the first article—to one in every sixteen admissions to the base hospital This figure he thinks, is if anything too low, because cases in the *medical and surgical wards are often not recognised* as psychological Like the authors of the two remaining articles—Dr M Boss and Dr Kurt Binswanger—he urges the need for closer coöperation between consultants so that cases in which neurotic symptoms are grafted on the residue of an organic illness—healed gastric ulcer or an attack of sciatica or lumbago—will not be wrongly diagnosed and thus wrongly treated Boss cautions his fellow psychiatrists about their approach to their medical colleagues physicians, he *reminds them*, are descendants of the old medicine-men, and demi-gods are jealous of their godhead This is a *caution* which might well work both ways, mutual forbearance achieving harmonious liaison between physician and psychiatrist

Psychiatric cases are treated in special wards in the Swiss base hospitals, there is also a psychiatric clinic attached to each group command, in which cases sent from the unit can be examined and treated sent to military boards, or otherwise disposed of Early psychotics, neurotics and psychopaths form the bulk of the patients, in most of them the illness has been present before they were called up, but symptoms have been evoked or exacerbated by *the* strict conditions of military

ANGLO-RUSSIAN ALLIANCE IN MEDICINE

THE Russians today, beyond all other races, are using fully our renaissance inheritance, the experimental method They have shown again and again that they are willing to try new things to discard what is useless for their purpose and to hold fast to what they find good In their present struggle they are gaining experience of mass woundings which may prove of high value to us in the future while we, with recent experience of raid injuries may have developed methods which would be serviceable to them The need to pool our knowledge led a group of doctors to call a meeting to establish a responsible body which would place and keep the medical professions of Great Britain and the U S S R in touch with one another The inaugural meeting, which was attended by the Soviet Ambassador, was held on Sept 10 at the Medical Society of London, with Sir Alfred Webb Johnson, president of the Royal College of Surgeons, in the chair The presidents of the other two Royal Colleges are also among the supporters of the movement M Maisky was in full sympathy, victory and future peace, he said, depends on the close cooperation of our two countries, and an alliance in medicine will be beneficial to both He comes of a medical family, and as a small boy contributed to his father's scientific work by looking after the laboratory guineapigs He left his hearers with no doubt of the value and importance of the task they were undertaking Dr Elizabeth Bunbury, who had been among those arranging the meeting, said that the idea had arisen when she and several other doctors, members of the Society for Cultural Relations with Russia, had found that Russian medical publications were not being thoroughly used in this country One task of the proposed committee, she suggested, would be to find translators and provide means of circulating Russian medical information She could already offer fifteen names of translators, and suggested that the Soviet Embassy might be willing to obtain medical literature from Russia, among which she mentioned the Red Army handbook The meeting agreed to form an Anglo Soviet Medical Committee, and elected Sir Alfred Webb Johnson as president, a letter setting out the aims of the body and asking for helpers appears on p 352 It was agreed that since the importance of any committee tends to be measured by the number and distinction of its vice presidents, a representative group of those who had shown interest in the project should be invited to serve in that capacity It was left to the organisers and the chairman to suggest an executive committee which could be submitted to members for their approval Lieut -General A Hood, director-general of the Army Medical Service, said that the War Office would welcome as much information as possible about Russian methods, especially those relating to evacuation of civilian population The medical directors general of the Navy and R A F had also sent messages to say they were in full support of the aims of the meeting All agreed that the organisation should be purely professional, distinct from other bodies, though, of course, willing to form liaisons with them where this was to the advantage of either Sir Philip Manson-Bahr remarked, in this connexion, that the tropical diseases bureau of the Medical Research Council had been publishing for more than a year, under the direction of Sir Harold Scott, *War Medicine*, which embraced the literature of the world, and much Russian work had already appeared in it The bureau has many Russian translators at its disposal and Sir Philip suggested that the new executive committee should work in close association with it Sir Harold, he said was anxious to obtain more Russian publications There was Russian news of two new virus diseases—a variety of nephrosis and an encephalomyelitis transmitted by ticks—about which it would be useful to have information Dr P D'Arcy Hart agreed that it be valuable to keep in touch with the bureau pointed out that the new committee wished to information from this country to Russia as well as to ceive it The chairman suggested that *War Medicine* well be translated into Russian Dr Aleck Bo felt that the new committee had a wider reference the mere exchange of views on war medicine it sh have an eye to peace, and should aim at arran exchange visits between us and our Russian collea Prof Wood-Jones asked that when the execu committee was formed the provinces might be borne mind A message of greeting was sent to the med secretary of the Academy of Sciences at Moscow and all medical workers in the Soviet Union, in which Anglo Soviet Medical Committee pledged itself to w for the utmost exchange of medical knowledge betw the two countries, now and in the future

SPLENECTOMY FOR ICTERUS GRAVIS NEONATORUM

SEVERE jaundice of the newborn often familial, is now regarded as one manifestation of a disorder of the hæmopoietic system of the developing embryo known as "erythroblastosis fœtalis" As its name implies it is a serious malady and had a high mortality until some years ago when Hampson asserted that normal adult blood serum contained a factor which counteracted the excessive hæmolysis present in icterus gravis and that intramuscular injections of blood or serum were of therapeutic value It seems likely that the disease terminates naturally after some days and hence if the infant can be tided over the neonatal period hæmolysis stops and the overactivity of the red cell forming apparatus—as shown throughout by the presence of large numbers of nucleated red cells in the peripheral blood—restores a normal blood picture in due course Unfortunately by that time irreparable damage may have been done to the nervous system because head retraction spasticity and mental defect are found in a proportion of survivors Hence workers have sought to improve upon Hampson's method and some have urged intravenous transfusion of matched blood as a preferable measure But severe forms of this always serious disorder are met with from time to time which fail to yield even to repeated transfusions and such a case successfully treated by splenectomy is recorded by Dr Hardwick and Mr Lloyd in this issue They mention that this heroic method was first used by Cooley in America in 1932 and again in 1935 It has the merit of stopping the hæmolytic process at once, in the present case this had apparently been achieved within 4 hours after operation, as shown by a blood count Transfusions before operation had failed to arrest the downward progress of child and red cell counts alike One transfusion was given after operation, and thereafter the red cells rose to normal figures, as is strikingly illustrated in the curves given Some authorities might differ from Hardwick and Lloyd when they say that splenectomy cuts short the disease process, because it is not yet clear whether hæmolysis or an excessive formation of primitive red cells is the primary fault Prevention of the disease in familial series by treating the mother during pregnancy with large doses of liver extract is sometimes successful and is an argument in favour of some disorder of blood formation as the fundamental lesion However splenectomy deals with the immediate postnatal problem of excessive hæmolysis, and as performed on this case in 20 minutes by the President of the Royal College of Surgeons on a baby of 8½ lb it represents a technical achievement of high merit leading to a result as satisfactory clinically as it is thought-provoking scientifically The programme for a practitioner faced with a baby who rapidly develops the severe

OFESSIONAL PROBLEMS IN WAR-TIME

REPRESENTATIVE BODY OF THE BRITISH MEDICAL ASSOCIATION

A CONFERENCE of representatives—the first since the tbreak of war—was held in B M A House on Sept and 12 with Dr H G DAIN in the chair During e course of the conference the annual general meeting as held under the chairmanship of Dr THOMAS FRASER Aberdeen at which the gold medal of the association as presented to Sir Kaye Le Fleming in recognition of tinguished work for the association and for the ofession

MEDICAL PLANNING

In presenting the annual report of Council to the presentatives Mr H S SOUTTAR told of exciting days d nights in the past year The great hall where the nference was held would have been lost by fire but r the skill of the janitor in dealing with incendiaries he Central Medical War Committee had provided ctors for the E M S and for the Services and was gaged to find many more The Medical Planning ommission had undertaken to study the future of edical practice, and was formed of the best group of en who could be found to advise on every branch of e subject The commission had the close cooperation the Royal Colleges and could claim he said, to represent the whole profession It was essential that in their ndings they should carry the whole profession with them d when a scheme had been drafted it would be submitted to every doctor in the country He believed at unless the profession was prepared to make its own heme, a scheme would be impressed on it by the overnment

In the discussion on various aspects of medical planning which followed it soon became clear that the ouncil would have had warmer support for the commission if instead of appointing it they had borne in ind the old democratic principle that committees to e representative must be elected Several of those resent spoke their minds on this point and no doubt lt the better for it, but in the end they were persuaded o admit that their commission however dubious its egetting was a fine baby of which much could be xpected In proof of this several duties were immediately laid upon the nursling Dr FRANK DALLIMORE Stockport) led off with the English doctor's hunting ry "Free choice" The family and the family doctor f their choice should still constitute the primary unit n the health service of this country, he felt and the Medical Planning Commission should be invited to regard his as a fundamental principle They were so invited—em con Dr NORTON STEVENS (West Suffolk) asked or an early interim report from the commission There vas bound to be delay he said before the final deliberations of the commission would be available and this nterval would give a good opportunity for discussion Otherwise there might be resentment of any scheme dopted by the commission no matter how good it was Mr SOUTTAR assured them that no report would be ssued until the whole profession had been consulted ut he was equally clear that there would be no interim eport though he undertook that members of the ssociation should be fully informed of progress Prof R M F PICKEN remarked that "early" was the most erious word in the motion, and reminded the meeting f the controversial subject matter before the commission nd of a few practical obstacles connected with paper and rinting In the end it was agreed the commission hould be expected to publish interim reports from time o time

Mr J S HUTCHISON (Halifax) moved that no further hanges should be made in the conditions of medical ractice until opportunity had been given for full discussion by all members of the profession The increase n the panel to include those with incomes up to £420, e said had been thrust on the profession without opportunity for discussion and the council should give the meeting some assurance that this would not occur again for no other reason than because it was the duty of all doctors to safeguard the interests of colleagues away on active service He was supported by Mr H J MCCURRICH and the motion was carried

Mr E H RICHARDS (Stoke-on-Trent) proposed that in view of the efforts of some political bodies and groups of doctors to further the introduction of a state medical service the association should be prepared for such an event and should forthwith consider essentials of administration and maximum remuneration His motion was carefully qualified by a clause indicating that by taking such a step the meeting would be expressing no opinion for or against a state service but by the very mention of such a thing he had let a serpent into the doocot which in happier days would have provoked stirring words The meeting however was being kept sternly to time by the chairman and the explosions detonated were not in the old H E tradition Major R SCOTT STEVENSON did remark that it was time someone said bluntly that a state medical service was not the policy of the B M A Not he seemed to feel, that official circles paid proper attention to the association's policy as set out in the well-known grey book there it was specifically recommended that the first extension of panel practice should be to the dependants of insured persons this had been ignored in favour of an extension of benefit to those under the £420 income limit Dr G W MILLER reviewed the association's policy since 1920 showing that it had been modified to suit events 'Everything we do he said is subject to the laws of evolution But a false impression had lately got abroad that the B M A was ceding the position it had always taken up in regard to a state service During the last war he had been told that a state service was inevitable yet it had not come Dr H W POOLER suggested that the motion should be accepted since it made no suggestion that affected the policy of the association but merely asked that the profession should be prepared if a Government scheme was put before them Neutrals were apt to be overwhelmed when an attack came He believed that opinion in favour of a state service had in any case been gaining ground within the profession, he had found that in Derby over 50% of doctors were in favour of such a service, and among the 25–40 age-group the proportion was 70% Mr MCCURRICH thought that if the profession went half-way to meet a state service they would be in trouble In replying Mr RICHARDS pointed out that if the policy of the association was to be overridden it was as well to be prepared with a state scheme but his motion was lost

OPHTHALMIC BENEFIT

A motion by Brighton protesting against the recommendation of the Ophthalmic Group Committee that non-insured persons and dependants with incomes between £250 and £420 per annum should be included for treatment under the national eye service was answered by Mr N BISHOP HARMAN The committee he said had sent out a questionnaire to every ophthalmologist on the B M A list and had had 481 replies to the 870 letters these showed a high majority to be in favour of the scheme and of the increase in the fee from 10*s* 6*d* to 15*s* 6*d* which the committee recommended Mr MCCURRICH who presented the motion suggested that the man with an income between £250 and £420 could afford to pay a specialist fee once every two or three years and that the change would create an unwarranted restriction on private practice which was unfair on those men who were away with the forces and had no chance to consider it Dr F A ROPER (Exeter) wanted the motion referred back to Council and Mr A. S GOUGH (Watford) said severely that the specialist services must sink or swim with the rest of the profession Mr BISHOP HARMAN pointed out that the Government had already forced a change in the insurance limit on general practitioners could the meeting refuse a similar increase to ophthalmic surgeons? It seemed they could for the motion was carried

MEDICAL ORGANISATION

Dr HUTCHISON (Halifax) proposed that the divisions should organise themselves into discussion groups for the consideration of the future of medicine and that the results of their deliberations should be forwarded to the central body for assessment and publication The service Among 100 cases examined at one of the clinics Boss found 6 neurological cases, 11 cases of epilepsy and other organic diseases, 6 alcoholics, 13 mental defectives, 31 schizophrenics, 15 psychopaths, 12 neurotics, 5 manic depressives and 1 malingerer Pure neurosis, he found, was rare, most neurotic symptoms appearing in cases of psychopathic personality The large number of schizophrenics is related to the fact that the men in this army group had been recruited from a region where insidious schizophrenia is known to be frequent This is an interesting observation in itself Lack of communication and the curious pride and seclusion of the Alpine dwellers makes intermarriage in some Swiss valleys common, and a high incidence of schizophrenia in a given region is thus probably associated with hereditary rather than environmental factors Malingering is very rare Brun found only two cases among many hundreds of psychopathic cases Disposal of psychopaths and neurotics is as difficult in Switzerland as here The three writers agree that no general rule is possible, every case must be treated on its merits To discharge all neurotic cases would prove too great a drain of man power from the small Swiss Army, and the same may well be true of larger forces Brun found it worth while to treat selected cases by psychotherapy Others are sent into auxiliary service which may be of two kinds, one belonging to the armed forces, and the other being a kind of labour service comparable with our Pioneer Corps The armed auxiliaries are mostly employed in guard duty which is apt to be tedious everywhere, and especially in peaceful Switzerland, and is unsuitable for most neurotics The labour service gives better results, but the accumulation of psychologically unstable people has its dangers Common-sense measures in the treatment of neurotic reactions include removal to other units of soldiers who cannot get on with their existing superiors, transfer of others from units where service is monotonous to units where they can have interesting technical training, transfer of those who are homesick to units nearer their own people All such measures are easily applied, but often neglected, not only in the Swiss army, they are only possible, of course, if the psychiatrist knows the special circumstances in each case

In addition to treating or disposing of the misfits, the "front-line" psychiatrist attached to the group clinic is expected to supervise the psychological atmosphere in the units of his group He should collaborate with the officers in command to create and maintain a healthy mental environment among the troops, he trains officers and those of non commissioned rank in the principles of mental hygiene, and helps to discover and remedy difficulties or grievances The cases quoted are comparable with those seen among soldiers by psychiatrists elsewhere, and the experience of these Swiss doctors can be applied to cases in our own Army serving at home Refusal to serve in the forces is a punishable offence in Switzerland, however, so that psychiatrists there have also to deal with the psychopathic patients among the conscientious objectors tried by martial law

EXAMINATIONS FOR TUBERCULOSIS

REPORTS from the Surgeon General's office indicate that the army of the United States is now committed to a routine X-ray examination of all recruits Full-size paper films were used in a preliminary investigation, reported by Edwards and Ehrlich,[1] of 16,150 recruits in the Southern New York District It was found that a team of three, consisting of a technician and two dark-room assistants, could operate at a rate exceeding one exposure a minute, the wet films were read by a physician and the results passed on to the medical board within an hour All recruits with abnormal films were referred to the municipal chest centre for complete clinical and radiological overhaul, as a result of which a number were passed as fit for service, those rejected incl (0 43%) with active pulmonary tuberculosis, (0 63%) with arrested lesions Rejection of the group was based on the chance that such lesions break down under conditions of military service the preliminary survey 35,210 more recruits were mined by the same method between Jan 15 and 31, 1941 Of these 389 (1 1%) were rejected on of pulmonary tuberculosis

The costs came to $23,614 for 16,150 men or $ per head The full-size paper films accounted $12,961 of this total (the materials costing several as much as those required for miniature screen p graphs) The national scheme for the radiol examination of recruits in the U S A is therefore c and Edwards and Ehrlich do well to emphasise what lack of it cost the country after the last war They to Spillman's estimate[2] based on an analysis of stati data from the U S Veterans Association, that the co the government of a case of tuberculosis in a veter the last war has been about $10,000 per man to da Using this figure, they compute that their cases of tuberculosis detected at the cost of $23,614 represent saving to the government of about $1,720,000 It mus be borne in mind, however, that though pensions for the patient or his family would be saved by the rejection of recruits with tuberculosis, the rejected men would still, in many cases, require treatment at the cost of the state But early diagnosis means a better chance of cure, and this in itself would mean considerable saving of sick-pay and of the cost of sanatorium treatment—as the experience of the firm of Philips Metalix in Holland has shown

AMMONIA AND THE GAS MASK

DURING an air-raid in London a year ago the con necting pipe of an ammonia condenser was punctured by a fragment of flying metal and 75 people in a crowded shelter suffered (7 of them died) from inhaling ammonia gas Dr Caplin who saw the results[3] says that no harm was taken by anyone wearing a civilian respirator, whether a member of a first aid party called in to help or a shelterer with the sagacity to don his mask at the first suspicion of an acrid smell He quoted a Ministry of Home Security pamphlet to the effect that any of the A R P respirators, although not designed for the purpose, does in fact afford some protection against ammonia gas Since that was written the Ministry has thought well to issue a special warning (H S C 161/1941) against this comfortable fallacy These respirators give a certain degree of protection against immediate dan from ammonia, but when they are worn subsequently the ammonia is liberated from the container in con centrations which may give rise to serious discomfort or even danger This effect is produced even when ga free air is drawn through the container, but if it shou occur in the presence of a war gas the wearer is com pletely deprived of protection He will be unable t wear the respirator because of the ammonia given o as he breathes through the container, and so will b exposed to the full effects of the war gas War respira tors should not therefore be relied on for protectio against ammonia, and if in emergency they have to be worn while escaping from an area seriously affected b ammonia fresh containers should be substituted as soo as possible for the old ones

THE division for the social and international relatio- of science of the British Association will hold a meeti on Sept 26, 27 and 28, at the Royal Institution Albemarle Street, London, W 1, when they will discu science and world order At the end of the meetin Sir Richard Gregory, F R S, the president, will announ a charter of scientific fellowship enefits of national insurance to persons earning up 420 per annum should not have been made without alting the practitioners themselves Dr Peter DONALD remarked that the actions of the I A C in fact been approved by the panel conference.

[1] Edwards, H R, Ehrlich D *J Amer med Ass* July 5, 1941 p 40

[2] Spillman, R *Ibid*, 1940, 115, 1371

[3] *Lancet* 1941, 2, 9

Dr Gregg became rhetorical in asking what insurance practitioners were dissatisfied about Was ecause the committee had protested with all their ht to the minister? Was it because they had told minister they would not accept his terms but would a panel conference? Or because they had asked a thorough investigation after the war? Or because y had insisted that any change in the cost of living uld be taken into account? Well said Dr Ernest ED, they were dissatisfied They felt the panel con- ence had not represented the feelings of the pro- on as a whole. Dr Frank Gray explained that the nmittee had been met by a flat refusal of any other ms by the minister The only answer would have en to refuse practice Did anyone suggest the pro- sion should have been advised to strike in the middle a war? Nobody did Mr P. W L Camps men- oned that in his division most of them had felt that it ould be a good thing to extend benefit to the £420 oup, but Dr Ward said that was not the feeling in s area In replying Dr Schiff said that it would ve been a good opportunity to hold a plebiscite of the hole profession. And why would it have been necessary go on strike? The profession could have asked for bitration In any case it should have been possible handle it in such a way that one's patients, instead of ying slyly 'Well doctor I see you ve got a rise,' ould have said "Well doctor I think you got a raw eal' The meeting shared his opinion and carried the otion

Motions from Leeds and Southport were combined and ccepted in the following form That the meeting dis- grees with the statement of the Government that the ependants of men serving with the forces are able to ay for their own medical attention and requests the overnment to provide as an urgent necessity adequate edical attention for such dependants This required o discussion

FOREIGN DOCTORS

Dr George Laurence (Swindon) told of two foreign octors in his area one of whom was a private in the ioneer Corps and the other serving in a shop He roposed that increased facilities should be given to efugee doctors to practise in this country for the dura- ion of the war and for such further time as was con- idered necessary Dr Anderson reviewed the position f refugee doctors the present regulations only per- utted them to practise in hospitals or in civil defence ervices A new order was now on the stocks which ould allow such doctors to practise as assistants but he association thought it would be unfair to absentee octors if the refugees were allowed to practise on their wn The motion as it stood was rather wide and Dr aurence agreed to its withdrawal

THE DOCTOR S MAID AND OTHER MATTERS

In appealing to the Council to request the Minister of abour to reserve at least one maid in a doctor s house r Arthur Beauchamp (Birmingham Central) asked hich man of them dared go home if he voted against ? There was no such hero present

Dr H S Pasmore (Kensington) moved that in the pinion of the meeting a general practitioner should be ttached to the staff of every teaching hospital to instruct e students in the art of general practice and to act as a nk between the hospital and the general practitioner rvices in the area This sensible and timely suggestion as referred to the Medical Planning Commission

Dr Taylor (Camberwell) moved that in the pinion of the meeting all institutions used as hospitals y local authorities should be administered under the ublic Health Acts (and not under the Poor Law) as a atter of compulsion instead of option as at present eople were often admitted to such hospitals against their ill he said and were then submitted to a means test rofessor Picken supported him—it was a reform long over- e This motion was also referred to the commission

Dr J A Pridham (Dorset) proposed that the Minister Health should be requested to confer on local authorities adequate power to prevent the spread of scabies Prof Picken agreed that this was an extremely important public health measure Scabies he said had been on the increase since two years before the war and had now reached epidemic proportions The meeting agreed to the proposal

---

SCOTLAND

DEATH OF A PAST M.O H FOR EDINBURGH

Dr William Robertson who died on Sept 8 in Edinburgh after an operation was medical officer for Edinburgh and Leith from 1923 to 1930 Graduating in Glasgow in 1887. he took his M D in 1891 and the D P H two years later and in 1923 he became F R C P E After holding house appointments in the Western Infirmary. Glasgow and the Perth Royal Infirmary he started general practice in Renfrew later moving to Perth where he was first dispensary and then health officer Returning to the west as M O H. for Paisley he reorganised the water department there putting an end to the recurrent outbreaks of typhoid In 1904 he was transferred to Leith where he had to deal with periodic outbreaks of smallpox originating in ships' crews. When plague appeared in the port he was publicly thanked by the Scottish Board of Health for his successful handling of the danger He was a pioneer in the examination of school-children starting also a child welfare service in Leith After the amalgamation of Leith with Edinburgh he became deputy M O H before taking full charge in 1923 Then he initiated a series of health exhibitions to serve both as a means of educating the public and of raising funds for the Royal Infirmary He had a firm belief in the value of posters and during his tenure of office many health slogans adorned the lamp-posts of the city He was lecturer in the school of medicine of the Royal Edinburgh Colleges and his precepts received wide currency in the pages of four books: Sanitary Law and Practice Meat and Food Inspection Public Health Law and Practical First-Aid He also wrote fiction including "The Stone of Dunottar a tale of the 45 and a volume of detective tales During the last world war he collaborated with Dr M J Oliver M O H for Roxburghshire in the invention of a steam disinfector which was used in the British Russian and Greek armies and afterwards in transatlantic liners Dr Robertson s cheerful disposition and vigorous personality are still green in Edinburgh s memory where he leaves a widow and daughter

A STUDY OF HYPERTENSION

In his Honyman Gillespie lecture Dr A R Gilchrist pointed out that directly or indirectly. more than 20% of people over fifty come to cardiac cerebral or uræmic deaths the outcome of long-sustained hypertension. In a general medical ward 15–20% of all admissions were attributable to high blood-pressure Systolic pressures of 150 mm Hg or over were abnormal, and so were diastolic pressures of 100 mm or more a diastolic pressure of 95 mm should be regarded as highly suspicious The average normal pressure at the age of twenty was 120/80 and at sixty 135/86 with a range of ±10% The well-known 1 2 3 relationship was found in most normal people, the pulse pressure being about half the diastolic and a third of the systolic pressure When the diastolic pressure was raised, owing to increased peripheral resistance this normal ratio was at first maintained when it failed and the systolic pressure began to fall the stage of cardiac failure had been reached The term hypertension should be restricted to diastolic hypertension since the important factor was the state of resistance of the arterioles Conditions such as complete heart-block and arteriosclerosis often produced a rise of the systolic pressure with a normal or low diastolic pressure These were not true examples of hypertension He paid tribute to the fundamental work of Goldblatt on the production of hypertension by renal ischæmia · the ischæmic kidney releases a pressor substance renin which causes vasoconstriction when activated the activated substance angiotonin has been separated and crystallised In the Goldblatt experiment a substance hypotensin was obtained from the normal kidney this acted as an antipressor substance Difficult and costly as it was to obtain, it had produced some impressive therapeutic individual medical practitioner, he said, was by virtue of his work too much detached from medical politics In an issue, 95% of the profession were unable to register an effective vote Small discussion groups of 6–10 members in every division in the country would allow every doctor to express his views There should be a coordinating body to present subjects for discussion The Medical Planning Commission might draw up a good scheme but it would have a much greater interest for the profession if the electorate had studied the questions for themselves Each group should have a leader who would send the group views to the division, the divisional committee would collate and subedit all the material reaching it, and send it to a central committee which would present the findings to the profession for consideration, after which a conference might be called This sensible and educative measure clearly had the support of the whole meeting, as Dr E A **Gregg** pointed out, it was important that the profession should not be presented with a mass of material which had been studied in detail by somebody else they should have had an opportunity to study the issues for themselves in advance After a few verbal amendments the motion was accepted unanimously

Dr A V **Campbell** (North Staffordshire) moved that the time was opportune to consider not only reconstruction in medical practice but also in the organisation of the B M A , and forthwith set out seven ways, no less, in which the association might be reconstructed These included the redistribution of divisions, regrouping of branches, the formation of area councils to appoint members of the central council, limitation of the number of years during which a council member might serve, and the adoption of trade-union methods by the whole profession when a division was engaged in a fight Faced with such a plethora of sweeping reforms the meeting was bewildered The chairman said he intended to let them vote on each section separately, but allowed the discussion to remain general There seemed to be a common feeling that in rural districts the divisions were apt to be unwieldy but, as Dr **Roper** pointed out, to save secretarial difficulties the divisions must be coterminous with local government boundaries Sir **Kaye Le Fleming** reminded them that there was already a retiring age for the council They had, in the association, a good machine, he said and added, from a heart apparently embittered by pool petrol, that if they paid less attention to the machine and more to the spirit they put into it, it would go better After some further discussion the meeting disagreed with North Staffs that the moment was opportune for the reforms recommended

CERTIFICATES

Here was a topic close to the heart of every general practitioner present Certificates have been multiplying at a rate to shame rabbits in the past two years, and the speakers were justly incensed Dr W A **Kirkpatrick** (Cleveland) proposed that the council should be asked to review the question of industrial certification under war conditions At present, he said, it was hard to know what to do when asked for certificates by an industrial concern, some doctors refused to give them, others gave them without charge, others charged for them Who ought to pay for such certificates? If the patient, the fee must be small The national service officer might be able to give a more appropriate fee, but had he power to pay at all? Dr G C **Anderson** said he was in communication with the Ministry of Labour about the certificates required under the Transfer of Labour order He had suggested on behalf of the association that in each area an official—preferably a medical man—should be appointed to whom cases of doubtful certification could be referred He had understood that the certifying factory surgeon would be appointed and would receive a fee but the Treasury had refused the expenditure Complaints had also reached him from the divisions about Attendance Bonus certificates for one-day absences He had been in touch with the secretaries of the Mining Association and the Mineworkers Federation and had told them that he would advise the profession against giving such certificates because with a one-day illness there were not as a rule sufficient clinical data to make a diagnosis This decision had borne fruit since it had been decided that absence for one day should not disqualify for an attendance bonus Moreover, the Essential Work order, absence from work for a no longer disqualified for wages With regard to multiplication of certificates, he had suggested that should be some coordination between Government d ments demanding certificates, and that before any certificate was required the departments should co with the Ministry of Health and with the association thought doctors should not be required to give certifi for milk for children under 5 years of age, or for milk invalids, or to witness signatures on certificates C W **Somerville** was worried by four varieties certificate those demanded under the Wor Compensation Act, which could be better given by factory surgeon for a fee of 5*s* and those dema by employers, by friendly societies, and by sch The attendance officer could deal with the sc children For the others some uniform action charge were needed Dr A W **Weston** said the doct first duty was to treat the patient and his second certify him fit for work There were patients wanted to change their work and to use the doctor as lever He always refused to oblige them, a doctor could certify a man as fit for his job, but had no call to cl jobs Dr H S **Howie Wood** warned the meeting about unscrupulous secretaries of friendly societies who would make a N H I certificate do where the patient ought to buy a private certificate The motion was carried

Dr **George McFeat** (Lanarkshire) invited the meeting to view with concern the apparent apathy with which representatives of the association permitted ever increasing certification to mount unhindered, to the detriment of general practitioners This seemed a little hard in view of Dr Anderson's account of his battles, but it enabled the mover to describe the fate of the doctor with twenty or thirty people in his surgery when asked in turn by the same expectant mother for a certificate for milk, a certificate for glucose, and a certificate for wool to knit into the traditional tiny garment Dr J W **Bone** agreed about the burden and asked the divisions to send in detailed information of their difficulties Dr W N **Leak** struck a new note by pointing out the difficulty that employers had, in the absence of a doctor's certificate, in deciding whether absence for one day was due to slacking or to some other cause This was important, he said, from the point of view of utilisation of man-power, for it had been shown that one-, two or three-day absences accounted for half the absenteeism in industry After this airing of the subject the motion was withdrawn

EXTENSION OF MEDICAL BENEFIT

A motion by Camberwell, proposed by Dr P H **Taylor**, that the meeting approved in principle the extension of N H I services to cover the dependant of insured persons with incomes up to £400 was oppo by Dr **Gregg** as being an issue too large to be decided in a hurry, and on the advice of Dr **Bone** the meeting passed to the next business Dr F W **Cheese** (Ea Kent) moved that the conference deprecated acti being taken by the Government on matters concerning the medical profession without first consulting repr sentatives of the profession, and this was accepted Watford, however, was less inclined to blame the Govern ment than the Insurance Acts Committee for not keepin the local committees adequately informed during th negotiations, being of the opinion that by skilful lead ship and publicity the present unhappy position could have been avoided, and moved, through the lips of Mr **Gough**, that the executive committee should sho proof that it was taking all possible measures to prevent a further unfair exploitation of the terms of service of its insurance practitioner members It was true, he said, that the Government had undertaken to review the whole question of the capitation fee, after th war, as from the ground floor, but if the profession wasn't careful it would find itself going from the ground floor to the basement, and taking in the dependant of insured persons at bargain-basement prices. The meeting shared his apprehension and supported Watford

Dr. C I **Schitt** (City) introduced a long and reproachful motion on the same topic, pointing out to the I A C that the increase accepted on behalf of the gen practitioners was no increase at all and that extension o

enefits of national insurance to persons earning up
20 per annum should not have been made without
lting the practitioners themselves Dr PETER
ONALD remarked that the actions of the I A C
n fact been approved by the panel conference ,
Dr GREGG became rhetorical in asking what
nsurance practitioners were dissatisfied about Was
cause the committee had protested with all their
t to the minister ? Was it because they had told
minister they would not accept his terms but would
a panel conference ? Or because they had asked
thorough investigation after the war ? Or because
had insisted that any change in the cost of living
ld be taken into account ? Well said Dr ERNEST
D, they were dissatisfied They felt the panel con-
ce had not represented the feelings of the pro-
on as a whole Dr FRANK GRAY explained that the
mittee had been met by a flat refusal of any other
s by the minister The only answer would have
to refuse practice Did anyone suggest the pro-
on should have been advised to strike in the middle
war? Nobody did Mr P W L CAMPS men-
ed that in his division most of them had felt that it
ld be a good thing to extend benefit to the £120
p , but Dr WARD said that was not the feeling in
area In replying Dr SCHIFF said that it would
e been a good opportunity to hold a plebiscite of the
le profession And why would it have been necessary
o on strike ? The profession could have asked for
tration In any case it should have been possible
andle it in such a way that one's patients, instead of
ng slyly "Well, doctor, I see you've got a rise,"
ld have said "Well doctor I think you got a raw
l" The meeting shared his opinion and carried the
tion

Iotions from Leeds and Southport were combined and
epted in the following form That the meeting dis-
ees with the statement of the Government that the
endants of men serving with the forces are able to
for their own medical attention and requests the
ernment to provide as an urgent necessity adequate
lical attention for such dependants This required
discussion

FOREIGN DOCTORS

)r GEORGE LAURENCE (Swindon) told of two foreign
tors in his area, one of whom was a private in the
neer Corps, and the other serving in a shop He
posed that increased facilities should be given to
ugee doctors to practise in this country for the dura-
n of the war and for such further time as was con-
ered necessary Dr ANDERSON reviewed the position
refugee doctors , the present regulations only per-
tted them to practise in hospitals or in civil defence
vices A new order was now on the stocks which
uld allow such doctors to practise as assistants, but
association thought it would be unfair to absentee
ctors if the refugees were allowed to practise on their
n The motion as it stood was rather wide, and Dr
urence agreed to its withdrawal

THE DOCTOR'S MAID AND OTHER MATTERS

In appealing to the Council to request the Minister of
bour to reserve at least one maid in a doctor's house,
ARTHUR BEAUCHAMP (Birmingham Central) asked
ich man of them dared go home if he voted against
There was no such hero present

Dr H S PASMORE (Kensington) moved that in the
inion of the meeting a general practitioner should be
ached to the staff of every teaching hospital to instruct
students in the art of general practice and to act as a
k between the hospital and the general practitioner
vices in the area This sensible and timely suggestion
s referred to the Medical Planning Commission

Dr TAYLOR (Camberwell) moved that in the
inion of the meeting all institutions used as hospitals
local authorities should be administered under the
blic Health Acts (and not under the Poor Law) as a
itter of compulsion instead of option as at present
ople were often admitted to such hospitals against their
l, he said, and were then submitted to a means test
ofessor PICKEN supported him—it was a reform long over-
e This motion was also referred to the commission

Dr J A PRIDHAM (Dorset) proposed that the Minister
Health should be requested to confer on local authorities adequate power to prevent the spread of scabies Prof PICKEN agreed that this was an extremely important public health measure Scabies he said, had been on the increase since two years before the war and had now reached epidemic proportions The meeting agreed to the proposal

SCOTLAND

DEATH OF A PAST M O H FOR EDINBURGH

Dr William Robertson, who died on Sept 8 in Edinburgh after an operation, was medical officer for Edinburgh and Leith from 1923 to 1930 Graduating in Glasgow in 1887, he took his M D in 1891 and the D P H two years later and in 1923 he became F R C P E After holding house appointments in the Western Infirmary, Glasgow, and the Perth Royal Infirmary he started general practice in Renfrew later moving to Perth where he was first dispensary and then health officer Returning to the west as M O H for Paisley he reorganised the water department there, putting an end to the recurrent outbreaks of typhoid In 1904 he was transferred to Leith where he had to deal with periodic outbreaks of smallpox originating in ships' crews When plague appeared in the port he was publicly thanked by the Scottish Board of Health for his successful handling of the danger He was a pioneer in the examination of school-children, starting also a child welfare service in Leith After the amalgamation of Leith with Edinburgh he became deputy M O H before taking full charge in 1923 Then he initiated a series of health exhibitions to serve both as a means of educating the public and of raising funds for the Royal Infirmary He had a firm belief in the value of posters and during his tenure of office many health slogans adorned the lamp-posts of the city He was lecturer in the school of medicine of the Royal Edinburgh Colleges, and his precepts received wide currency in the pages of four books Sanitary Law and Practice, Meat and Food Inspection, Public Health Law, and Practical First-Aid He also wrote fiction including "The Stone of Dunottar" a tale of the 45, and a volume of detective tales During the last world war he collaborated with Dr M J Oliver, M O H for Roxburghshire, in the invention of a steam disinfector which was used in the British, Russian and Greek armies and afterwards in transatlantic liners Dr Robertson's cheerful disposition and vigorous personality are still green in Edinburgh's memory where he leaves a widow and daughter

A STUDY OF HYPERTENSION

In his Honyman Gillespie lecture Dr A R Gilchrist pointed out that, directly or indirectly, more than 20% of people over fifty come to cardiac, cerebral or uræmic deaths, the outcome of long-sustained hypertension In a general medical ward 15–20% of all admissions were attributable to high blood-pressure Systolic pressures of 150 mm Hg or over were abnormal, and so were diastolic pressures of 100 mm or more , a diastolic pressure of 95 mm should be regarded as highly suspicious The average normal pressure at the age of twenty was 120/80 and at sixty 135/86 with a range of ±10% The well-known 1 2 3 relationship was found in most normal people, the pulse pressure being about half the diastolic and a third of the systolic pressure When the diastolic pressure was raised, owing to increased peripheral resistance, this normal ratio was at first maintained , when it failed, and the systolic pressure began to fall, the stage of cardiac failure had been reached The term hypertension should be restricted to diastolic hypertension since the important factor was the state of resistance of the arterioles Conditions such as complete heart-block and arteriosclerosis often produced a rise of the systolic pressure with a normal or low diastolic pressure These were not true examples of hypertension He paid tribute to the fundamental work of Goldblatt on the production of hypertension by renal ischæmia the ischæmic kidney releases a pressor substance, renin, which causes vasoconstriction when activated , the activated substance, angiotonin, has been separated and crystallised In the Goldblatt experiment a substance, hypotensin, was obtained from the normal kidney , this acted as an antipressor substance Difficult and costly as it was to obtain, it had produced some impressive therapeutic results. Dr. Gilchrist mentioned emotion as one of the most important extra-renal factors causing hypertension; it was on this account, he said, that little reliance could be placed on a single determination of blood-pressure. Blood-pressure readings taken during sleep provided a control for assessing the importance of emotion; the emotion itself might be due to direct excitement, or to repressed resentment and an undercurrent of fear and anxiety. Organic lesions of the central nervous system, particularly of the midbrain and brain stem, had sometimes been recognised as being associated with hypertension. Hormonal influences were known to be operative in other cases, particularly in association with medullary and cortical lesions of the suprarenal glands; the pituitary and the ovaries might also be responsible for hypertension. The value of œstrogenic hormone, or its synthetic substitute stilbœstrol, in controlling vasomotor phenomena at the climacteric was well known, but opinions differed on the influence of these hormones on menopausal hypertension. The symptoms, he found, might be relieved, but the blood-pressure remained high.

RÔLE OF RENAL ISCHÆMIA

The hypertension of renal ischæmia might, Dr. Gilchrist went on, be induced in a variety of ways. Possibly obliterative vascular disease in the kidneys might produce the same effect on blood-pressure as the Goldblatt clamp: if the renal arteries or arterioles were sufficiently obstructed, ischæmia was produced and hypertension resulted, but if the renal arteries escaped the patient might live to a ripe old age in spite of widespread arteriosclerosis. When severe narrowing of the renal artery was found in patients with hypertension widespread arterial change was sometimes found within the kidneys; but it was not always possible to say which came first. Coarctation of the aorta was a clear-cut example of the influence of renal ischæmia on blood-pressure: hypertension only occurred when the aortic constriction was proximal to the origins of the renal arteries. The hypertension occasionally observed during the course of congestive heart failure could also be attributed to impaired renal circulation. He mentioned obstruction to urinary outflow as a cause of hypertension; this was most frequently due to enlargement of the prostate, when daily readings of blood-pressure might provide a sensitive guide to the patient's welfare. Hydronephrosis even when unilateral, renal calculi, and urethral strictures had also been found in association with hypertension. In unilateral hydronephrosis secondary changes in the opposite kidney were permanent, so that removal of the hydronephrotic kidney was usually harmful because it threw a still greater burden on the remaining kidney. The commonest inflammatory disease of the kidney was acute pyelonephritis; the inflammation led to obliterative vascular disease in the kidney and this in turn to hypertension which was often severe. Acute Bright's disease he believed to be an uncommon cause of persistent hypertension in later life; among 820 consecutive admissions to his wards he had had 4 cases of acute nephritis and 125 of chronic hypertension.

In England Now

A Running Commentary by Peripatetic Correspondents

AMID the luxury of modern hospital life the young resident often knows little about the ordinary routine which will be the background of his work. When I was posted to an isolated R.A.F. station as surgeon I found that there was an enormous and unsuspected hiatus in my knowledge which had not been filled by the course for the fellowship.

One of my tasks was to help to transform an Irish castle into a small hospital. One of the first difficulties was equipment. After a few months we were handsomely provided for, but our original surgical stock-in-trade was a saw, many scalpels, a few pairs of dissecting and artery forceps, and no fewer than twelve towel-clips (but no towels). A typed inventory of equipment to come contained the item: Tables, operation, 18. "Eighteen?" We said "they must have big ideas for us here." We wondered where on earth we could put them. Would there be eighteen surgeons operating all at once? Or would a smaller number, a mere dozen or so go to table after table in rotation as at an clinic? But further investigation showed that we merely to receive towels, operation, 18. From baseless fabric of this vision created by an misprint, we descended to reality and realised t could at least now properly employ the clips, t possibly not all at once. The second great difficulty in the orderlies, who, though willing were ignor hospital routine and methods. One gradually got their heads the meaning of asepsis, but it was disco ing, when operating under a local, to find that my assistant had left the theatre to get a glass of water the patient. Later on, equipment began to roll in we no longer had to heat the steriliser over the kit range. One morning our prize piece of apparatus arri —a high-pressure steam drum-steriliser. We st up this awe-inspiring affair with considerable trepidat watching the pressure-gauge with anxiety, and I for noted carefully the quickest way to the door. But method was mastered, and as the orderly in charge of sterilisation was enveloped in clouds of steam whe work, I felt that he should be remustered to "Engine driver, steam." I was comforted by the thought t there was a large supply of gentian-violet and tannic aci jellies in the next room. There was one incident which might have been alarming. When the steriliser was being used to disinfect some bedding a blanket became wedged in the opening connecting the outer with the inner steam chamber. When the pressure gauge failed to register the orderly applied more heat with great enthusiasm and not until the inner jacket had crumpled like paper did he realise that there was something amiss. Fortunately the technicians were able to make it serviceable again.

A fatherly government gave us much equipment, gloves and gowns, but failed to supply us with caps or masks. I needed these, and as there seemed no other way of getting them I undertook their manufacture myself. Recollection of theatre nurses at work enabled me to remember how to make swabs, how to fold gowns, to fold pieces of gauze, to pack gloves, and even, after much experiment, to make little swabs containing talcum powder to go with the gloves. But I quailed at the thought of sewing caps and masks. When I tried to enlist the aid of my wife and her sewing machine, she politely but firmly declined to act except as a consultant. I found a new respect for womankind when I tried to fathom the intricacies of Mr. Singer's great invention (or was it M. Thimmonier?). Making masks from gauze and tape was the first step, and was fairly easy. Cap making was another matter altogether, but it was simplified by unearthing some old pillow-cases, worn out in the centre only. By dint of cunning manœuvres suture lines were neatly buried and a number of caps turned out. It was a triumph of new-found technique; an anastomosis was done on a cap which was too small, and a succe ful resection performed on one which included my ears as well as my head when tried on.

All this made me wonder whether surgeons haven't more to learn from their wives than their traditional sha in the compilation of the index. Could not the sewin machine be adapted for surgical use? Chromic catg could perhaps be supplied in sterilised reels; think of th time that might be saved in sewing up the rectus shea after a laparotomy. A modified French seam would b almost ideal for resection and anastomosis of the intestine; by comparison with the Singer suturing machi the Petz sewing-clamp would indeed seem clumsy an out of date. Cannot our surgical inventors do somethin in this line for us?

P.S.—I have no financial interest in any sewing-machine company.

For the last few weeks I have been doing a locum a a municipal sanatorium, the first time I have been in a sanatorium for years, and I must say I am disappointed. I feel as one who had been privileged to watch the apo in action might when he goes into a rather opulent we end church. The buildings, the food, the nursing w excellent, the site glorious, the gardens a paradise informality, but I missed the spirit of the early fath that intense drive to make fit, that fiery crusading that whistled as the winds did through the sanato in the earlier part of the century. The patients did n work except a little desultory potato peeling. Do till believe that lungs heal better when working n occupied and contented brain, that sanatorium the first step in rehabilitation of potential chronics, he aim of treatment is not mere health but useful that even a sanatorium can produce something l on the asset side ? Here the last word in deadess, they even burnt their food refuse Then the of a sanatorium as a university to train the more sical of us in a way of life seems to have been comly abandoned There were no lectures, the nts didn't even take their own temperatures, al going out after three or four months didn't know their morning or evening temperature should be the thermometer is the one dial on their dashboard can warn them of coming trouble Then again I that no frantic effort was made to seize those drifting the few months when they could be saved by an ack pneumothorax Many of the patients here were -strain casualties—that lad of nineteen who worked is lathe for over twelve hours a day from last May till ruary is as much a war casualty as if he had licked sandy hand of death at Dunkirk

* * *

t would be worth the mass psychologists' while to ermine why among the manifold urges of man the act of a new combination of ideas or an outstanding sonality or both should cause men and women to act nascent molecules, to strive and strain with fiery husiasm which inevitably tails off into the commonce commercialism of the last crusade or codfish nstianity I saw this pristine fire in the early days the Scout movement when men like Roland Phillips l Anthony Slingsby lived and died in a blaze of zeal, th compels me to admit I saw it in Nazi youth, in a er key I see it recur about every five years in the lage cricket club Women don't seem to get it in the ne intensity and are much more long-winded It may just a part of the cogwheel evolution of man, but of things I am sure, that active hourly participation ither a sign or a cause of health in these urges and that re is a deadly sequence of general approval, funds, bilisation, decay Cables of gold can only anchor ships the spirit

* * *

My dear John and Jane —So you've been reading the *ncet* students' number Well, I never ! It certainly esn't seem like seventeen years ago that I was pulling ur father's leg because of his twins and he was persuading e to stand as godfather And now you both write to me ying you're going to start medicine and please will I ll you what the boys and girls are like at the different ondon hospitals as you've read the prospectuses and ey all seem very much the same, and the staffs have all t just about as many Sirs as each other I'm sorry say I don't know all the London hospitals, and even e ones I do know I'm not quite certain about But ll have a try, and if you show this letter to any doctors u happen to meet, they'll certainly tell you where I'm rong and where (if anywhere) I'm right

Ladies first *King's* girls are tall and strong and ean-looking, and have a higher proportion of blondes an the general population They are nice and sensible d good at games And I don't see how many of them n avoid getting married *U C H* girls are very ever, and I think a lot of them are socialists, because ey think about other things besides work They don't ix very much with the boys so I suspect both the boys d the girls are a little bit shy The *Royal Free* girls e the smallest ones of all Some are very clever, and few are good at games But lots of them are awfully od at knitting and cooking and seeing if your socks are ended I expect you'll think I'm prejudiced because ur Auntie Mabel was there—and perhaps you're right

Now for the boys *Bart's*, remember, is very, very, d And if you've been old—and famous—for very, ry long, well, you'd expect to be a little proud of it it as one of the Royal Free ladies said to me the other y, when you get underneath their shells you find ey're just as nice—even nicer—than the others *y's* I like the Guy's boys They're tough and good games and full of beer And they don't pretend to very clever But the funny thing about it is that spite of it all I'm not sure that they aren't really the verest of the lot *Thomas's* boys are very big In fact, your Auntie Mabel says they're all giants In other ways I think they're about half way between Bart's and Guy's *King's* boys look the same as Thomas's one's to me *George's* men (I dare not call them boys) prove that you can wear a fancy waistcoat and be a good doctor at the same time *U C H* boys are clever at physiology and biochemistry and blood-proteins, but for all that I wouldn't mind going there if I was ill I can't tell you about *Mary's* or *The London* or any of the others, not because they aren't very good hospitals, but simply because I don't know about them I suggest you drop a line to your Uncle Tom Cobley and see what he's got to say on the subject

Well my dears, I've done my best, and if you can't make head or tail of this letter you're a sillier pair of billies than I thought

Your loving Uncle Jim

"It'll clear up," said the manager confidently, joining us at the hotel door I was pessimistic, but Popplethwaite said he was sure the manager was right, he felt it in his bones We left the hotel in a drizzle of rain, but as we struck along the country road we could see the banks of mist rolling slowly up the hill sides, and every minute the increasing light revealed more of the detail in our surroundings Popplethwaite gave a whoop of joy as a break appeared in the pall of cloud and released a shaft of brilliant sunlight which picked out a forest on a mountain ridge As we walked along the lakeside road the sky was transformed from leaden grey to dazzling blue, and every stage in the birth-pangs of a belated but glorious day was reflected in the face of the water Steam arose in thin clouds and struggling wisps from the drenched road and flies began to drone in the moist heat As we climbed out of the valley through the foothills only small pools here and there hinted at the metamorphosis which we had witnessed little more than an hour before We toiled up the hill carrying our coats on our arms The afternoon was well advanced but the sun beat down on us as though he had been at his zenith No bird sang Only the flies flouted the conspiracy of silence, driven to a frenzy by the vibrant heat An astonishing variety of butterflies failed to excite any comment A gorgeous Red Admiral fluttered clumsily across our path unheeded From time to time we stopped, ostensibly to admire the magnificent panorama which was opening out behind us as we climbed, but actually to allow us to recover our breath and to wipe from our faces the sweat which dripped from our eyebrows and trickled over the lenses of our spectacles "Could I persuade you to take a cup of tea with me ?" I inquired, looking at Popplethwaite as I moistened my lips "And how," he replied, scanning the quivering horizon like Robinson Crusoe We laboured on in silence broken only by occasional sighs and smothered groans Suddenly we accelerated our pace both of us having seen in the distance a farmhouse, and in the garden a crooked notice-board from which a piece of paper fluttered When we were within twenty yards of it Popplethwaite darted forward with an alacrity that astonished me He was still standing in front of the notice when I reached him panting and sweating Printed in Gothic letters of various colours (seemingly in an attempt to achieve originality) were the words.

NO TEAS NO EGGS NO CIGARETTES

In these changing and uncomfortable times there is something strangely comforting about the Moor, she is so solid and permanent, seeming to smile tolerantly upon the puerile activities of man If bombs fall on her she hastens to cover the holes with heather expeditiously and unfussily rather as a sensible mother might wipe away the milk spilt by a sick child My latest visit was all too short Staying at a place where I have often stayed I dined off duck and green peas and breakfasted off sea-trout There was a canter on a stocky little mare who rapped on well, as we say, and a swim stark naked in a moorland stream Afterwards the spotted dogs put up a vixen who smiled at them over her shoulder and led them a dance of several hundred yards before giving them the slip by the simple expedient apparently, of dematerialising herself and becoming absorbed into a rock I have a feeling, Mr Schickelgruber, that the Moor is laughing at you

Letters to the Editor

MEDICAL COOPERATION WITH RUSSIA

SIR,—An Anglo-Soviet Medical Committee has been formed to arrange the interchange between the medical profession of this country and the Soviet Union of the latest material on the clinical and scientific aspects of medicine Such an interchange can be of considerable value at the present time to members of the profession in both countries and we believe that a large number of doctors in this country would be willing to cooperate in the work Those interested and those prepared to assist by summarising and abstracting English articles and translations of Russian work should write to the hon secretary, Anglo-Soviet Medical Committee, c/o Royal Society of Medicine, 1, Wimpole Street, W 1

Lord DAWSON OF PENN, F R C P
Dr W E GYE, F R S
Sir GOWLAND HOPKINS, O M , F R S

Sir ALFRED WEBB-JOHNSON, P R C S
Sir CHARLES WILSON, P R C P

THE GROUP O DONOR CARD

SIR,—We wish to draw attention to the risks that may be run when the recorded blood-group of a volunteer blood donor is accepted without confirmation There are now so many members of emergency donor services available that when a volunteer is required for an urgent transfusion the chances of one with a donor group card coming forward are high If there is extreme urgency and the donor presents a group O card there may be a temptation to use his blood without further test Danger is, of course, entirely obviated if a direct compatibility test is employed, but in an emergency the doctor, who often finds the collection of a sample of a patient's serum for the test a tedious affair, may be tempted to dispense with it and rely entirely on the evidence of the card that the volunteer is a universal donor He may regard it as an additional safeguard that this donor has been used before, not realising that the destination of the previous donation might have been a plasma or serum pool where a knowledge of the group is immaterial and re-checking is often dispensed with

Errors in mass grouping have been estimated to be as high as 10% in some places, and these may be due either to technical or to clerical mistakes In our experience the commonest mistakes have been due to the presence of cold agglutinins—group O being reported as A, and A as AB—but we have recently had an instance of a group AB donor being issued with a group O card in error by the clerk There are also many other possibilities of clerical error even with the most careful checking Since one of the main purposes of mass grouping in war-time is to segregate into an emergency list selected individuals of group O who live or work near the bleeding centres and who can be called on at short notice, the question arises whether the issue of the group O card should be permitted to the emergency donor without an independent confirmation of the group

The possession of a group card gives the volunteer donor a real sense of responsibility and it is to him a source of satisfaction to know that he is registered in a national transfusion service Moreover, the card is of value when he wishes to transfer to another district, and for these reasons it would be undesirable to limit the issue of these cards in any way We feel, therefore that the cards of guaranteed universal donors should be clearly marked "Group O confirmed" with a rubber stamp or preferably a punch, and that this mark should have a definite significance throughout the country The fact that the group had been checked by an accepted standard would make the risk extremely remote This system of confirmation could, of course, be extended to all blood groups

In conclusion however, we wish to stress that a direct compatibility test *should* be made in all cases

SULPHANILAMIDE IN FIRST-AID

SIR,—There has recently been discussion not sulphanilamide should be applied to woun first dressing—e g , by a first-aid party, before is transported to hospital An attempt has be in this laboratory to study the question experim

Rabbits were anæsthetised and a penetrating made through the muscles of the thigh, with one through the skin on the medial surface and the other lateral surface When completed there was a central about ¼–½ in square and about ¾ in deep su lacerated muscles over an area about 1¼ in square 0 2 g sulphanilamide as a dry powder was smeared over one side (medial) of this wound, and the skin on each side was closed by sutures The rabbits immobile by barbiturate anæsthesia After 5 hours, or 24 hours, the rabbit was killed and samples for estimation were taken from the wound cavity and from adjacent muscle on the side (lateral) opposite to the amide Suitable controls were also taken to det concentration of sulphanilamide in the animal as a In this way it was possible to determine how much of sulphanilamide had reached the depths of a wound of above dimensions Briefly, it was found that by *diffusion the sulphanilamide had penetrated well* in one of the wounds, had *penetrated slightly* in one fifth, and ha *not penetrated at all* in the remaining three fifths of the cas

In a recent paper (*Lancet*, 1941, 1, 786) it was shown that sulphanilamide does not penetrate by local diff into living tissue more than 2–3 mm , and that even in dead tissue its diffusion during the first 6 hours is limited If there are convection currents in the wo fluid, however, it might be carried much further down t wound cavity

The application of these results to first aid p is properly a matter for surgical experts to decide , b it seems that unless the sulphanilamide were worked down into the wound cavity with a spatula or insufflator, which is not advisable under first aid conditions, its action would usually be restricted to checking bacterial growth on the surface of the wound If the casualties are to receive operation within a few hours it does not seem justified to go to much trouble and expense to secure such a limited result If treatment will be long delayed as under battle conditions, the procedure may be m valuable

National Institute for Medical Research

SOLDIERS AT CIVILIAN V D CLINICS

SIR,—Dr Erskine says that a soldier diagnosed bacteriologically as gonorrhœa was diagnosed "urethritis" when he arrived at the military hospital exactly the same occurred when a man was sent from my clinic My pro forma stated the diagnosis, and that I ha begun treatment with sulphapyridine so that the m might be rendered uninfective as soon as possible, as th might be delay in reaching the military V D hospital

I agree with Colonel Osmond that every soldier shou bring a pro forma duly completed, but in many ins these forms are either not brought or improperly filled in I have on several occasions made out a pro forma, a when the man attends again he does not bring it, a another has to be filled in and completed from my car

The V 44 can be folded once and kept in the pay bo and takes up no more room than a photo I know th the men would not consider it a burden , in fact th would welcome the idea, especially those who have be having "surveillance tests" in different parts of t country for nine months or more without ever hav their final test , thus, I believe, losing proficiency in certain cases

I am glad it is now forbidden to give sulphapyrid in suspected cases of gonorrhœa in the Army, and w it could also be stopped in civilian cases I am sure t if Army patients cease to attend civilian clinics specialists at the clinics assume the man or unit , moved , this is obvious I imagine that the dermatologist, R A M C , will have much the difficulty as the civil V D specialists when a man g for his "final test" Having been a specialist d tologist, R A M C , in the 1914–18 war I can appre both points of view I am satisfied that the ex on (those actually treating cases) as distinct from administrative section of R A M C dermatologists welcome a simplification of the present difficulty the lines suggested

atients such as commercial travellers and actors are e properly comparable to the present Army in regard mobility than are merchant seamen Deductions ed on a practical experience of smooth working with civilian transfer card V 44 for 20 years cannot fairly dismissed as theorising

Bradford　　H H WHITE

SIR —In his reply (Sept 6) Colonel Osmond has shown at he recognises certain shortcomings of the pro ma which should be sent with a soldier when he attends ilian clinics but he does not appear to favour the e of form I 1247 (or V 44) which contains the essential formation required To quote from his letter " [Most] my M O 's of today are the G P 's of yesterday " who e ' notoriously bad at filling up forms " Since there are " multiplicity of forms which he has to complete," it ould save paper and time in unnecessary summarising a man attended a civilian clinic with his I 1247 form s the necessary information would then be available t would lead to more efficient treatment and would save much time for the M O of the civilian clinic who is now unable to complete his work in the official hours on account of increased attendances due to Service cases The ggestion that a soldier has so much kit that he cannot rry an I 1247 is irrelevant, for he can collect and return is form just as simply as he can collect and return a o forma I have sometimes had the cooperation of my M O s who support my point of view, and I believe is unofficial method has been helpful to all parties regard to Colonel Osmond s third point I have efinite evidence that many men who cease to attend gularly are not receiving treatment elsewhere, and I el that some solution to the problem on the lines I have ggested should and could be found On this point I ould ask whether a soldier suffering from V D has rect approach to his M O or has he first to explain s condition to an N C O ?

In defence of the merchant seaman I would say that aving regard to the conditions of his employment I ave found him a most satisfactory attender And he es bring a V 44 with him '

I would assure Colonel Osmond that as he knows, I ave already given more than ' a second thought " to ese problems, and I would suggest from my experience dealing with these men that it is the present official egulations which " though admirable in theory, are nworkable in practice '

Queen Anne S reet W 1　　DAVID ERSKINE

CALCIUM AND PHOSPHORUS STUDIES IN NORMAL PEOPLE

SIR —Dr Robertson throws a great deal of literature t my head almost all of which is irrelevant to the oints I raised in my last letter

Calcium content of the tissues —Is the tissue calcium at the ame level under an intake which just meets normal require ents as under a high intake ? This is the only issue The terature he quotes is quite irrelevant to this question Moreover, a man suffering from pronounced arteriosclerosis (it oes not matter whether his calcium deposits are primary or econdary) has a great deal more calcium in his system than normal person How did this calcium reach the system, if s Robertson maintains an overdose is impossible because the nwanted calcium is rejected via the fæces ? I have also eferred in my last letter to positive feeding experiments low was this possible ?

Advantages of a high calcium intake —Again the literature e quotes is irrelevant to the point I raised Obviously, if the alcium intake is so low as to lead to disastrous results, it is n intake which falls below minimal requirements But this not the issue I stated that no data are available to judge hether an excessive intake of calcium which he calls optimum ' is more desirable than one which meets minimal equirements None of the authors he quotes are dealing ith this point, and my question still stands

Renal excretion of calcium —In his paper he states that " the ealthy body rejects in the fæces whatever calcium it does not equire He admits now that under an excessive intake ome of the superfluous calcium leaves the body via the kidney This is an important fact, because the superfluous calcium circulating in the blood and coming in contact with tissues already saturated with the substance predisposes to deposits We found that in certain circumstances the kidney may perform eighteen times more work than necessary in removing superfluous calcium Bollah found that in some cases of arteriosclerosis, a condition which we know is very prevalent, the kidney may excrete more than 1 5 g of calcium daily Let Robertson calculate, say, for a period of ten years the amount of kidney work under a renal output of 1 5 g per day and 0 4 g per day He will find that the amount of extra work is enormous

Detection of calcium insufficiency —Robertson says " If large sections of our population are ingesting less calcium than is necessary for equilibrium between intake and output, then they are getting insufficient calcium " But such data do not exist On the contrary, there is definite evidence that in the bulk of the population there is a balance between intake and output, for a permanent negative balance must give rise to abnormal clinical manifestations In our cases, under a calcium intake between 0 39 and 0 579 g there was a balance between intake and output These figures agree well with those of Sherman and others Under this intake there was no retention of calcium, but under a higher intake there was retention of this substance This is the crux of the *whole problem Is it more desirable to have a calcium intake* which just maintains a balance between intake and output, or one which stores calcium in the body to the greatest possible extent ? We followed the matter up (Harris, Ireland and James, *J Physiol* 1941, 99, 370) and found that under a high base intake the calcium is stored in the body, but it replaces some of the nitrogen (protein), a good many other things might have happened which we have not ascertained

There was a time when a similar stunt to that of calcium was organised in regard to protein It was then maintained that a large section of the population was suffering from malnutrition because the protein intake did not come up to a certain high standard which we know now is quite unnecessary In our paper just mentioned we found that potassium is retained in exactly the same way as calcium Is the bulk of the population suffering from potassium deficiency ? We found also that there is retention of protein to a very great extent (High Blood Pressure, London) There is little doubt that what applies to calcium, potassium and protein applies to a great many other substances, but if all these substances were pushed, each to the fullest extent of its storage capacity, each competing with the other for the limited space in the tissues and blood stream, each ousting the other, conditions would be created which would hardly be favourable to optimum health I am much concerned with this problem We found that in cases of high blood pressure a low protein intake which was just sufficient to balance the output lowered the blood-pressure and in other ways improved the condition of the patients But we found that the level of protein in the tissues is lower under a low than under a high protein intake And I have asked myself whether in the long run a low protein level in the tissues might not be undesirable Years of clinical observation have led me to believe that an intake which just meets minimum requirements, at least so far as middle age is concerned, is also the optimum intake We all know too that frugal livers, who are moderate with food in general (I presume such a person is also moderate with calcium), live longer than hearty feeders,

Of course these are mere clinical impressions But so abyssmal is the ignorance of the people who are concerned with calcium requirements that they are not even aware that there is a problem as to what really constitutes optimum requirement Robertson is only able to quote authorities, but some of the seniors have given exact figures—so many milligrammes of calcium per kilo weight as constituting optimum requirements Would they come forward and give us the evidence on which these calculations are based ? Have they proved that life is prolonged by their " optimum ' intakes ? The whole calcium extravaganza shows that laboratory work unchecked by clinical observation is dangerous

Calcium retention in the middle-aged —Let us visualise two reservoirs, one holding a pint and the other a gallon, both of them full to capacity An added inflow of the same amount of fluid in one as the other will give the same outflow in both Obviously in the fully saturated cases the middle aged cannot differ from the young and Robertson s table IV is therefore irrelevant to the whole question

Osteoporosis —I agree that glandular disturbance has something to do with this condition In one case reported by Meulengracht the calcium intake was actually satisfactory Osteoporosis is a rare condition All this proved that osteoporosis due to calcium deficiency alone is even more rare (if there is such a condition)

An unduly high standard of calcium requirement has been arbitrarily set up, entirely unsupported by evidence, and 15–20 million people have been declared to be suffering from calcium deficiency because their intake is supposed not to have come up to this standard I challenged them to produce a dozen adults who show manifestations of calcium deficiency they have not done so In these circumstances it is an insult to the intelligence of your readers to ask them to believe that a large section of the population is suffering from calcium insufficiency

Liverpool I HARRIS

SULPHATHIAZOLE IN STAPHYLOCOCCAL PNEUMONIA

SIR,—The excellent result of very heavy dosage with sulphathiazole in the case reported by Major McCollum in your last issue is of extreme interest as it is, as far as I know, the first reported case of recovery from severe staphylococcal lung infection due to a drug of the sulphonamide group, although successful treatment of staphylococcal tracheobronchitis has been reported (Shulman 1941) McCollum states that primary bronchogenic staphylococcal pneumonia is a non-septic form of pneumonia This is not quite clear to me, it is certainly a suppurative lung lesion with microscopic if not gross abscess formation in the lung, and is not infrequently accompanied by a positive blood-culture This was so in 50% of the series of Chickering and Park (1919), and a number of other cases with positive blood-culture have been reported—e g, case 1 of Burgess and Gormly (1930), Apert and Porak (1911), Clark and Barysh (1936) The onset of staphylococcal pneumonia is sudden but there is nearly always a preceding upper respiratory infection, the commonest being virus influenza The prognosis is not always as gloomy as McCollum suggests Bullowa and Gleich (1938) give the mortality as 41% under two years, 12 5% between two and twelve years and 54% in adults In this connexion it is important to note that staphylococcal lung infections fall into two distinct groups There is the fulminating type with mortality 50–80% (Reimann 1938, Chickering 1937), and a benign type of low fatality in which radiographically, if not clinically, there is cavity formation in the lung The larger series of cases reported do not differentiate between these groups in giving figures, but a study of reported cases shows these two groups very clearly

TELL YOUR AGE AND JOB

SIR,—To ensure a balanced representation of medical opinion it would be helpful if the ages and types of work of all the members of every medical council and committee in this country were published and, in future, these data might be added as a routine

Great Bookham, Surrey RICHARD A. MANCLARK

IN QUEST OF A CURRICULUM

SIR,—The two leaders in your Students' Guide enshrine many ideas which I have harboured, both as a student and since qualification If translated into action, preferably after the war, your suggestions would raise the whole standard of our profession The articles on medical education in the Dominions and the various countries on the temporarily Nazified continent of Europe give scope for much thought I do feel a return even be it a modified return, to the old apprenticeship system is very desirable There is an unwholesome gulf between the clinical experience of the general practitioner and the specialist or teacher, whereas their work should be complementary It would be advantageous if the newly qualified did jobs in both voluntary and municipal hospitals to get a good bird s-eye view of clinical in its acute and chronic aspects As you suggest, time in the curriculum should be given to o anæsthetics, public health and pædiatrics, and vague discussion of the more abstract details of pat medicine and surgery which are of value only to specialist I should like to advocate a course of fi for all first-year clinical students, at present newly qualified men pass out of hospital with but mentary knowledge of the treatment of common emergencies such as accidents and sudden faints, or of arrest of hæmorrhage by pressure on the classical bl points A course in dietetics is also urgently n I know of no medical school which provides such a co and yet one of the commonest questions from patien "What can I eat, doctor?" Thanks to articles in popular press many laymen are more conversant dietetics than some doctors Yet knowledge of f values and balanced diets is of the utmost value practice There should, too be more instruction psychiatry Mental medicine is playing an increa important part in medicine A course of ten lect with six demonstrations of cases does scant justice to a vital subject A good psychiatric background is esse tial to the proper understanding of organic disea There should also be a few lectures on the history of medicine, for doctors should know something of their ri heritage from the centuries

Norwich J B GURNEY SMITH

CARE FOR HOME GUARD CASUALTIES

SIR,—May I add another cause for complaint to those given by your correspondents? It is not permissible to enrol men for medical services only but we are expected to train in first-aid and stretcher drill such as are willing to take on this as an extra duty, and even so, if and when required such trainees would be in the fighting line and unavailable as bearer squads In districts such as this, with areas of moorland, attention to casualties in reasonable time would be impossible For the pres I have arranged that 50% of each platoon shall have some instruction in the handling and transport of wounded but this is not good enough and every battalion ought to have a medical unit exempt from other duties The whole question of medical personnel and equipment urgently requires revision Is it too much to ask that you would approach leading members of the profession whose opinion would carry weight and get them to impress on the War Office the necessity of giving the matter attention, and that without further delay?

P L W WILLIAM,
Battalion M O H G

Cornwall

Public Health

From the Annual Reports

SOME METROPOLITAN BOROUGHS

Hampstead is one of the smallest but wealthiest of the metropolitan boroughs with a population of 71,250 and a rateable value of £1,570,000 In 1940 its birth rate was 11 1 and infantile mortality 49 Of the 796 birth in the borough 92 were illegitimate Maternal mortality was high (4 8) but the stillbirth-rate very low (11 6 Owing to the nature of its population, the percentage of illegitimate births is always high in Hampstead and from this we should expect high stillbirth infanti mortality and maternal mortality-rates, but the development of child welfare and the altered attitu of the public towards illegitimacy are gradually reducing its mortality though it still remains well above what it should be Of the 1159 deaths registered in the borou 136 were accredited to "other violence"

In 1939 the metropolitan boroughs of *Fulham* (popula tion 135,800) and of *Wandsworth* (population 330,00 agreed in their infantile mortalities of 47 and in ab ence of fatality from measles, but the birth-rate of the former was 13 5 against 11 99 of the latter and the adju death-rate 12 6 against 10 92 Notifiable diseases we very low in both boroughs The cancer mortality Fulham was 2 05 and in Wandsworth 1 79 and tu culosis mortality 0 84 in Fulham and 0 69 in Wandswo

Dr John Macmillan in his 1939 report for Woolw gives a detailed list of samples, taken under Food

Acts both formal and informal which were found on analysis There were only three prosecutions regard to abstraction of fat from milk, in which fines ew shillings were imposed to encourage this highly tive form of swindling which is particularly prevalent e London area In one case a vendor was fined £1 £1 1s cost for selling milk from which 21% of the ad been abstracted In London especially in the fruit season there was a heavy demand for cream as abstraction of cream from new milk cannot be cted—in which it differs from the more common ustration of adding water—it is not an offence for ch the vendor can be brought to book unless the traction reduces the fat-content below the legal ndard We therefore have to allow the trade to n milk to some extent but when it is overdone and ected the penalties for doing so should be severe art from milk faults found in food samples are mainly to carelessness dirtiness illegal use of preservatives orrect labelling and ' new business ' An example this which occurs five times in Dr Macmillan's list coloured fruit-flavoured jellies coated with sugar sold glace fruits

Dr A G G Thompson s report for 1940 of the borough Lambeth is a short typewritten document revealing e influence of severe and continuous aerial bombard- ent on the public health The statistics deal with e whole year the first half was a time of great stress, ie second of violent commotion in which the ordinary usiness of public-health administration had to be hanged to cope with conditions of active military rather han civilian hygiene The Registrar-General s estimate of the population in the middle of the year—that is before the Battle of Britain started—was 210 650 against the 1939 estimate of 270 800 At the end of the year the number of persons holding ration cards was 160 000 so he statistics based on a population of 210 650 really elate to a population which in the course of the year had windled by more than a third and are therefore of no alue for comparison The year was an extraordinarily uiet one for infectious diseases Amongst the 1286 eaths registered in the borough there was only 1 from phoid 8 from cerebrospinal fever 1 from whooping- ugh 4 from measles and 7 from diphtheria Epidemics typhoid and other water-borne diseases were to be spected from the serious damage done to the water- upply system by the bombardment but they did not aterialise There were 38 deaths from suicide 32 om traffic accidents and 734 from other violence, which st we may presume were in the main due to enemy tion. The general death-rate was 19 72 compared ith 13 37 in 1939, but as over a sixth of all deaths were ie to other violence " and the reduction of popula- on would be mainly due to the exodus of persons in tle risk of dying except by violence the high rate in no nse reflects the health of the borough The corrected rth-rate was 15 52 against 13 17 in 1939, though the umber of births notified sank from 4814 to 3674 Taking l factors into consideration this rise in the birth-rate still puzzling As the stillbirths numbered but 114 id deaths in the first year only 144 (giving the very low fantile mortality-rate of 47) of which 42 were accredited premature birth and 37 to malformation it is clear at the war had little influence in causing premature bour

CHELMSFORD

The most interesting feature in Dr J Mervyn Thomas's port is that of the 367 deaths which occurred during 40 in the borough 116 were of persons over 75 years of e The general death-rate was 11 1, though a high antile mortality of 57 accounted for 28 deaths or arly 8% of all deaths There was no maternal mortality, ly 1 death from measles in the old zymotic group and deaths from violence The estimated population of e borough was 33 040 its density 6 9 persons per acre d 3 3 per inhabited house No special reason is given the detailed analysis of seven samples of water taken Nov 11, 1940 All the samples were satisfactory

BURY

According to Dr G M Lobban this county borough oved a record year for health in 1940 The official imate for the mid-year population was 55 310 which the lowest since 1919 and is possibly below reality, though low birth-rates and migration south, both mainly due to the depression in the cotton industry, have been decreasing the populations of the Lancashire towns for some years There was an increase in the birth-rate to 13 1 and of the death-rate to 17 5 but infantile mortality fell to 65, tuberculosis mortality to 0 42, and maternal mortality to 1 32 Of the 970 deaths registered 520 were in persons aged over 65 years 321 in those aged 45–65 82 in those aged 1–45, and 47 in those below one Cancer caused 131 deaths, giving the high rate of 2 37, but only 8 of the deaths were in persons below 45 years of age Of the 377 deaths attributed to cardiac and vascular disease only 10 were in persons below 45 years of age whilst 270 were in persons over 65 years of age Of the 47 infant deaths 25 were due to prenatal causes The incidence of infectious diseases was low the only one above average being cerebrospinal fever with 11 notifications and 1 death

Infectious Disease in England and Wales

WEEK ENDED SEPT 6

Notifications—The following cases of infectious disease were notified during the week smallpox 0 scarlet fever 958 whooping-cough, 3029 diphtheria 820 paratyphoid 182, typhoid 46 measles (excluding rubella), 911, pneumonia (primary or influenzal) 107 puerperal pyrexia 117 cerebrospinal fever 128 poliomyelitis 29 polio-encephalitis 3, encephalitis lethargica 3, dysentery 66, ophthalmia neonatorum 71 No case of cholera plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Sept , was 1287 including scarlet fever 120 diphtheria 239 measles 41 whooping-cough 578 enteritis 23 chicken pox 39 erysipelas, 24 mumps 6 poliomyelitis 2, dysentery 17 cerebrospinal fever 20 puerperal sepsis 14 enteric fever 29 german measles 1 polio encephalitis, 2 other diseases (non infectious), 44 not yet diagnosed, 88

Deaths—In 126 great towns there were 4 (2) deaths from enteric fever 3 (0) from measles 1 (0) from scarlet fever 18 (2) from whooping-cough 17 (0) from diphtheria 41 (4) from diarrhoea and enteritis under 2 years and 3 (0) from influenza The figures in parentheses are those for London itself

Bristol and Exeter each reported 1 death from enteric fever Ilford had 3 deaths from whooping-cough There were 6 fatal cases of diarrhoea at Birmingham and 5 at Manchester

The number of stillbirths notified during the week was 150 (corresponding to a rate of 30 per thousand total births), including 6 in London

---

Parliament

The Stamp Peerage

At the next sitting of the upper house Lord Moyne will move that the writ for the present Lord Stamp (Trevor Charles Stamp, M B Camb) should be issued to him as third holder of the peerage The first Lord Stamp's eldest son Mr Wilfrid Stamp was with his father in the fatal air-raid and was killed at practically the same moment The Law of Property Act 1925 laid down that, where two persons have died in circumstances rendering it uncertain which of them survived the other. the younger shall be deemed the survivor in matters affecting the title to property The House of Lords on Sept 10 decided to accept this principle for another purpose Mr Wilfrid Stamp will be regarded as having momentarily succeeded to his father s peerage his widow and three daughters will therefore be recognised as holding the status and title proper to this rank. As he had no son the succession passes to the first Lord Stamp s second son

Road Traffic

In a debate on the national war effort on Sept 11 Mr ELLIS SMITH asked for more efficient transport facilities for the sake of the health and well-being of factory workers and deplored the effect on production of the increasing rate of road accidents Colonel J J LLEWELLIN joint parliamentary secretary to the Ministry of Road Transport, said the Government regarded the staggering of hours in factories as the main remedy for crush at the peak period This it was hoped to achieve by agreement between employers and workpeople More transport vehicles were being made the Army had undertaken to return 700 buses, and single-decker buses were being adapted to take 32 seated and 30 standing Short-distance travel was being discouraged by raising the minimum fare The increasing rate of road accidents was deplorable, the fewer the number of vehicles on the road the higher the accident rate seemed to rise It was difficult to know what to do about it, if, as he believed, the increase was due largely to the unfortunate fact that in war-time people—perhaps necessarily—were a little more reckless of life and limb Further it was impossible to have the same police supervision All road users must share the blame for the lack of road sense Lectures thereon had been reinstated in the school curriculum this autumn

QUESTION TIME

Increased Capitation Fee

SIR ROBERT GOWER asked the Minister of Health whether the doctors on the panel of the National Health Insurance scheme were to receive an increased panel payment rate, and whether he could make a statement on the subject —Mr ERNEST BROWN replied Yes, Sir From January next the doctors under the National Health Insurance Act will receive a capitation fee of 9*s* 9*d* instead of 9*s* per insured person

Transfusion Supplies

SIR ROBERT GOWER asked what use had been made hitherto of the accumulated supplies of transfusion blood, and whether the existing quantities were regarded as adequate — Mr E BROWN replied Considerable numbers of blood transfusions, for which both blood and plasma are required, have been given in dealing with air raid casualties and Service patients, and increasing use is being made of transfusion therapy in hospital practice generally I am advised that the existing donor panels and their associated blood stores, together with the plasma produced at the processing centres, should provide adequate resources for casualties on a considerably larger scale than was experienced last autumn and winter

Sanatorium Beds in Wales

Mr JAMES GRIFFITHS asked the Minister of Health if he had now considered the report of the Welsh National Memorial Association, and what steps he had taken to meet the deficiency of 400 beds at sanatoria and hospitals in the Principality —Mr E BROWN replied The shortage of institutional accommodation for tuberculosis in Wales, which is less than is suggested, has been receiving close attention and proposals are before me which it is estimated will provide 114 additional beds, by the erection of huts at two existing sanatoria and by structural extension at a third

Allocation of Medical Man-power

Sir E GRAHAM-LITTLE asked the Minister what was the present position of the Central Medical War Committee with regard to the allocation of medical practitioners to various civilian and military services, whether the new committee under the chairmanship of Mr G H Shakespeare superseded in this respect the C M W C, and whether a practitioner, dissatisfied with the decision of the C M W C might appeal to this superior committee —Mr E BROWN replied The C M W C continues to act as a supply committee in providing the doctors required by the various civilian and military services, and is not in any way superseded by the Medical Personnel (Priority) Committee, although in selecting the individual doctors it will naturally conform with any decisions taken by the Government on the recommendation of the Shakespeare Committee as to the order of priority in which the demands of the various services are to be met It is not intended that an appeal from a practitioner should be entertained

Stay-put Order for Hospital Staffs

Mr CULVERWELL asked whether, in view of the difficulty in retaining nursing, attendant and domestic staff in hospitals and municipal institutions, the Minister would include them in the schedule of undertakings under the Essential Work (General Provisions) Order, 1941, as being services essential to the life of the community —Mr E BROWN replied I have recently made an order under which persons employed whole time for more than twelve months as nurses in mental hospitals (where certain conditions as to rates of pay and conditions of service are complied with) are required to continue in such employment unless their services are dispensed with in accordance with the provisions of the order For the purpose of conserving the staff of hospitals this is preferable to scheduling hospitals as undertakings the Essential Work (General Provisions) Order, 1941. question of making a similar order applicable to generally is under consideration

British Social Hygiene Council

Mr RHYS DAVIES asked whether the Minister wa that this council was likely to curtail its activities o lack of funds, and would he take steps to prevent this ing —Mr E BROWN replied The council has acq me with their financial position, and I have suggested they should cooperate with the Central Council of Health Education which is the agency recognised by the Government for education on matters of health generally The council has welcomed the suggestion

New Orthopædic Units in Scotland

Dr H B MORGAN asked the Secretary of State for S land whether he could state the situation of the six new orthopædic units in Scotland, how many orthopædic surgeons were engaged, and the number of junior surgeons or medical staff appointed in each case, and whether these units were run on the lines recommended and approved by the Delevingne Committee —Mr T JOHNSTON replied The orthopædic units in question are at Stracathro Hospital, Angus, Princess Margaret Rose Hospital, Edinburgh, Peel Hospital, Selkirkshire, Larbert and Killearn Hospital, Stirlingshire, and Hairmyres Hospital, *Lanarkshire* There are 10 orthopædic surgeons, of whom 4 are employed whole time The junior staff consists of 1 junior surgeon who acts as registrar in each of the units, except Peel Other junior medical staff is attached to each unit by the medical superintendent according to the number of orthopædic cases under treatment, up to a maximum of 3 per 200 beds The answer to the last part of the question is yes

The Fortified Loaf

The proposal to add calcium to white flour has not been abandoned The fortification of white flour with vitamin B has already begun in certain mills supplying the South Wales area and will shortly be extended to other districts (Major LLOYD GEORGE replying to Sir ERNEST GRAHAM LITTLE)

Disablement Pensions

MISS WARD asked the Minister of Pensions (1) if he would make public the rates of pensions to be paid for permanent specific injuries arising from the present war, (2) whether, in assessing the compensation to be paid to women who suffered amputations as a result of the present war, he would take into account the added obviousness of the disability by comparison with men, discomfort in wearing artificial limb attachments, damaged wear and tear of clothing, loss of amenities of life, and the severe handicap in the prospects of matrimony, and the severe handicap in the domestic sphere, and if he would state the proportion of the award of 9*s* 8*d* per week paid as compensation for the loss of a leg and the foregoing items, and (3) who was responsible for the award of 9*s* 8*d* per week pension to women who suffer amputation of leg below knee with stump exceeding inches, seeing that an award of £1 per week was paid to 1914-18 war pensioners with exactly the same disability —Sir WALTER WOMERSLEY replied Assessments for specific injuries are given not as an absolute direction but for the guidance of medical officers in reporting on claims Assessment of disablement is by comparison with a normal healthy person of the same age and sex and takes into account all effects of the disabling condition It would be inappropriate to a the disabling condition an exactly similar amputation differently in the case of a woman and a man In the main the assessments now are the same as those in the 1919 warrant In certain cases they are higher and in others lower Assessments for amputation through the leg below the knee, with a stump exceeding inches, are normally 40% as against 50% in 1919 The rea is that the advance in surgery and in the design and fit of artificial limbs has been such that an assessment of 5 is no longer justified There is no case of an amputation which an award of £1 a week would attach in Great War where the New War award would be 9*s* 8*d* a week warrant of 1919 from which the rate of £1 a week is made no provision for women

Clothing Coupons

A supplementary issue of coupons will shortly be made children who are unable to benefit from the lower values assigned to the smaller sizes of clothing, while discussions are taking place with the representatives of indu s to ensure that they have sufficient coupons to meet essential needs In the meantime, industrial clothing ssary for the health or safety of workers may be obtained on free on certification by a factory inspector (Sir rew DUNCAN replying to Sir LEONARD LYLE.)

vacuees and inmates of institutions have the normal ration clothing coupons Charitable organisations wishing to ect coupons for knitted garments supplied to such persons uld apply to the Board of Trade for the necessary authority, ich will entitle them to use the loose coupons for making the purchases of wool (Replying to Mr CULVERWELL)

Medical News

yal Society of Medicine

On Friday, Sept 26, at 2 30 P M , Miss Ida Mann and Dr B D llinger will read a paper to the section of ophthalmology mustard gas injuries to the eyes in rabbits and men

ourse in Tropical Medicine

The London School of Hygiene and Tropical Medicine has ranged a five months course, beginning on Sept 22, to pre are postgraduate students for the diploma in tropical medi ne and hygiene granted by the English Conjoint Board

British Postgraduate Medical School, London

During the week Oct 13–17 Mr R Watson-Jones will give at the school a course of lectures and practical demonstrations on the treatment of fractures with special reference to war conditions Further information may be had from the dean of the school, Ducane Road, W 12

Royal Free Hospital

An A. M Bird postgraduate scholarship in pathology has been awarded to Dr C Thomas

Biochemical Society

A meeting of this society will be held in the School of Biochemistry, Cambridge, on Saturday, Sept 27, at 11 45 A.M., when short papers will be read

arpenden Auxiliary Hospital

On Saturday, Sept. 27, at 3 P M , Lady Malcolm Stewart will pen the new hospital in Carlton Road

risoners of War

The following R A M C officers have been posted as risoners of war —

T/Major D L Charters M B Glasg W S Captain T I V erguson L R.C P I W S Captain W G France M B Leeds, tain J B Fulton M B Manc Captain J E Gray M B Durh, Captain J G Jamieson M R C S W S Captain F L G one L R.C P I , and T/Major W S Sykes M B Camb

dical Honours

he George medal has been awarded to Acting Squadron-der Joseph MacCarthy, M B N U I

he R.N V R officers' decoration has been awarded to geon Commander T W Drummond, L R C P E, geon Commander H O Martin, L R C P E , and Surgeon nmander H E Hall, M.D Belf

nburgh Panel Committee

t a meeting of this committee held on Sept 9 a resolution passed, "That this meeting appreciates the action already en by the British Medical Association in endeavouring to e introduced into National Health Insurance the depend s of insured persons and, while keeping in mind this end, uld in the present emergency urge immediate action for the usion of the dependants of men serving in H M Forces "

ncer Act, 1939

ast year the Minister of Health extended the period wed to local authorities for the preparation of schemes viding expert diagnosis and skilled treatment for their cer patients He has now further extended this respite il March 31, 1942, but he urges authorities who have not ady done so to submit interim schemes in the meantime the present he feels efforts should be mainly directed making full use of existing facilities, by the payment of onable travelling expenses and by making widely known facilities which are available. To help patients in specially erable towns he is trying to establish cancer treatment res at E.M S hospitals outside the danger area But e centres will be a temporary emergency provision and will relieve the local authorities of their duty to make their arrangements for the diagnosis and treatment of cancer

REGIONAL MEDICAL OFFICER

ELSA ALDEN, S R N , S C M , H V
WOMAN INSPECTOR

MINISTRY OF HEALTH, REGIONAL OFFICE, CAMBRIDGE

THE first evacuation of school-children from London took place in September, 1939 Most of them were evacuated in school parties unaccompanied by their parents A civil-defence region consisting of nine administrative counties and four county boroughs formed to the greater part of its extent a reception area for this evacuation, and a total of 129,800 children were received During the quiet months that followed there was a drift back to London, but some 30% of the children remained In September, 1940, a second large-scale evacuation began, and by the end of January, 1941, the added population of the region numbered some 200,000 of which a large proportion were children either "unaccompanied" or accompanied by their parents

Investigation suggested that the number of children's beds in hospitals would be adequate for cases of serious illness but that additional accommodation would be required for minor sickness which would normally be nursed at home but could not always be nursed in billets Sick-bays were accordingly set up to meet this need From their earliest inception these sick-bays were reserved for cases of minor illness, and separate hostels were set up for healthy children, including difficult and unbilletable children, and cases of enuresis

The decision to set up a sick-bay was dependent on local needs and whether other sick-bays were available within a reasonable distance In general the provision was based on a standard of 5 beds per 1000 child-evacuee population Each sick-bay usually served a number of county districts under the general coordination of the county medical officer This permitted the pooling of all sick-bay accommodation within the county, and adjoining counties were linked up through the regional office of the Ministry of Health The day-to-day administration of the sick-bays rested with the local district council, but in one or two instances a county council set up and administered its own sick bays

By the end of the winter of 1939–40, 22 sick-bays with a total of 419 beds had been set up in the region During the summer months of 1940 a number were placed on a care-and-maintenance basis owing to the seasonal decline in minor illness, and others near the coast were permanently closed With the approach of winter those on a care-and-maintenance basis were reopened and further accommodation was also provided to meet the needs of the fresh evacuation from London By the end of February, 1941, 21 sick-bays with a total of 474 beds were available in the region, and 3279 children had been treated A summary of the principal ailments treated is in the table

As a general rule, each sick-bay admitted all types of case, but as a temporary measure it was necessary once or twice to set aside sick-bays for a particular purpose—e g , the reception of scabies, chickenpox, measles or whooping-cough The sick-bays had 10–50 beds, larger units were avoided because they increased the risk of infection, and seemed to be more often in quarantine than the smaller Most of the sick-bays were set up in unoccupied private houses because they needed few adaptations Other types of accommodation used included a disused cottage hospital, convalescent homes, a smallpox hospital and a hotel

In planning the layout, accommodation for both patients and staff had to be considered In choosing suitable rooms for wards a floor-space of 60–70 sq ft per bed was allowed No standard as to size of wards could be laid down but in general many small wards increased the difficulties of nursing, whereas too large wards tended to spread infection Where possible wards of 4–6 beds were chosen Separate bathroom and sanitation were necessary for the patients, and in sick-bays taking scabies cases a separate bathroom for these was desirable The surgery serving also as examination-room and dispensary was usually on the ground floor, and in some a minor-ailments clinic for evacuees was held An isolation-room for the segregation of suspected cases of infectious disease was also provided As the children were usually only confined to bed for a small part of their stay, where there was no separate playroom it was necessary to have a dining-room which could also serve as one Facilities for outdoor recreation were provided wherever possible

PERSONNEL

The number of beds in each sick-bay determined the number of nursing staff to be employed At least one, and usually two or more, state-registered nurses were employed, the rest of the staff being assistant or auxiliary nurses Many nurses working in these units were recruited from the Civil Nursing Reserve and were paid at the appropriate rates Members of the British Red Cross Society and St John Ambulance Brigade also served, and both nursing and domestic staffs were supplemented by voluntary workers The cases treated did not need elaborate equipment The usual sources of equipment were central and regional Government stores, supplemented by local purchase where necessary

The clinical care of the children was undertaken by local general practitioners, and one practitioner was usually nominated by the local medical war committee for this purpose, for it was generally preferable for one doctor to take charge of the treatment of all cases, more particularly where patients were sent in from a distance This doctor also controlled admissions and discharges. Payment for this clinical care for unaccompanied children was made through the pool administered by the local medical war committee, and a fee of 7*s* 6*d* per quarter was paid for each accompanied child, the parent contributing as much as could be afforded In one or two instances, the doctor was paid a retaining fee for general administration on behalf of the medical officer of health, but as a rule the local M O H took charge of the administrative arrangements himself

The county medical officer acted as coordinator for the sick-bay accommodation within his county, and by means of a system of weekly returns it was possible to correlate all the sick-bays in the region This regional correlation proved in practice to be extremely useful, for when sick-bay accommodation in one county was seriously depleted by an outbreak of infectious disease children were transferred without difficulty to sick-bays in adjoining counties Similarly, a sick-bay set aside in one county for cases of scabies could serve adjoining counties Consultants were rarely required for the minor ailments admitted Patients who became seriously ill were transferred to hospital, but it was occasionally necessary to call on the services of a general physician or an ear, nose and throat surgeon

ANALYSIS OF WEEKLY RETURNS OF 3279 CASES ADMITTED BETWEEN NOV 25, 1939, AND FEB 25, 1941

Skin conditions—		Observation for appendicitis	17
Scabies	886	Rheumatism	12
Impetigo and septic sores	806	Threadworms	12
Ringworm	85	Rickets	7
Eczema	8	Fractures (following treatment)	17
Boils	26	Scalds	15
Septic chilblains	11	Minor infectious disease and contacts—	
Others	71	Whooping cough	15
Enuresis (temporarily accommodated)	107	Influenza	20
Chest conditions—		Chickenpox	24
Bronchitis	57	Measles	17
Pleurisy	3	Scarlet fever	1
Asthma	21	Pyrexia	8
Pneumonia	9	Epilepsy	3
Malnutrition and debility	84	Other nervous disorders	9
Ear, nose and throat conditions—		Gastric conditions	10
Tonsillitis	62	Adenitis	3
Otitis media	55	Jaundice	6
Following tonsillectomy	46	Chorea	23
Coryza	50	Nephritis	11
Croup	5	Miscellaneous (including 105 admitted for uncleanliness)	116
Mastoiditis	3		
Injuries to ear	5		
Others	17		
Eye conditions	30		

It can be said, therefore, that these sick-bays have, in addition to assisting the general billeting arrangements, provided facilities for the early treatment of disease, and thus resulted in a saving of hospital beds

TREATMENT OF BURNS IN SPAIN

L G. Oliveros uses a cod-liver-oil ointment infrequent-dressings technique in the treatm burns, and he is well satisfied with the results in 7 first degree and 20 of the second and third (*Rev espan* 1941, 2, 170) The ointment contains 25 of cod-liver oil and 100 international units of vitami to 73 g of lanolin The burn is washed with and dried by light dabbing with cotton wool, b being left unpricked The surrounding skin is with 90% alcohol The burnt area is then covered a thick layer of the ointment and a sterile dressing applied With first-degree burns the dressing is with a flannel bandage, but with those of second or degree the dressing is enclosed in plaster of-paris, wi padding In either case the dressing is left untouched 8 days By then most first-degree burns are h Second and third degree ones need a second appli of ointment, which is put on without removing the remains of the first, only the surrounding skin being cleaned with spirit The dressing is reapplied e 8 days for as long as necessary The advantages cl for this method are absence of pain, avoidance of second ary infection, rapid separation of dead tissue, and suppl scars Its drawbacks are that it does not prevent shock, that folliculitis may develop in the surrounding skin, though swabbing with spirit largely prevents this, that there is a danger of secondary hæmorrhage, and that the smell is very disagreeable

---

UNIVERSITY OF LONDON —A statement in the students' number (*Lancet*, Aug 30, p 240) has led students to believe that there will be an additional final M B , B S examination in December, 1941 The examination referred to is the second examination and the next final examination will not be held till April, 1942

GERMAN STUDENTS' EXPENSES —According to the Deutscher Hochschulfuhrer for 1941 the fees of a medical student in Germany today amount to about R M 200 for each half year Other expenses such as books instruments come to another R M 30–100 Board and keep ranges from R M.120–130 a month, but the special arrangements available for needy students can reduce this to R M 65–90

Appointments

ME GUARD MEDICAL ARRANGEMENTS

A LAWRENCE ABEL, M S Lond, F R C S

GROUP MEDICAL OFFICER, HOME GUARD

WE are reminded almost every day and always by e Prime Minister when he speaks to us, that invasion this island is a virtual certainty That this will be rried out mainly by air-borne troops is almost equally rtain That these troops may land in considerable mbers and at several different points is shown by the perience of other countries The landing of a large umber of paratroops (120,000 fully equipped and armed en in six or eight widely separated districts is considered asible) would be more likely to occur in isolated ountry districts than in the centre of a town In town istricts the already established, well-equipped and well-taffed A R P and other medical services are capable of dealing with casualties among both civilians and Home Guard men but both civilians and combatants in country districts might be quite cut off from such aid, both in the immediate vicinity of hostilities and perhaps for several miles around My remarks therefore apply mainly to rural districts, though it must be borne in mind that even in towns severe damage may render even street to street communication impossible In any case, in a town the hospitals and first-aid posts are usually conspicuous buildings and likely to be easy and early targets and might soon be out of commission Therefore peripheral casualty collecting posts with adequate cellars should not be neglected in urban districts

It may be estimated that among any particular platoon of Home Guard men as many as 00% might be casualties within a few hours of the arrival of the air-borne force Wise as it may be therefore to have a number of trained stretcher-bearers every member of the Home Guard should be taught as much first-aid as is possible in the small time at our disposal, in order that each man may be able to help his pal It should be remembered that every member of the Home Guard, except a medical officer wearing a red cross brassard, is a combatant who has no Home Guard Medical Corps to come to his aid Each Home Guardman therefore stands an equal chance of being wounded, and by the same token an equal chance of being called on to carry out first-aid for his friend

The Home Guard Medical Service should be responsible for first-aid training and for treatment before hostilities The former will result in reasonable care of the wounded at the time of injury They should also be responsible for the establishment, staffing and equipping of casualty collecting posts in rural and sometimes urban districts where A.R P or other facilities cannot be relied on If both these functions are carried out it follows that arrangements will be organised for the transport of casualties from the battlefield to the collecting post, and for their care there for an indefinite period

FIRST-AID TRAINING AND IMMUNISATION

Each commanding officer should arrange that his medical officer should be given every facility to impart, and that every man in his battalion should attend to eceive, instruction in simple first-aid This should be with special reference to the treatment of wounds including fractures and hæmorrhage of burns and of pain Every man should be made to carry an 18 ft by 3 in roller bandage together with his first-field dressing and should be taught how to improvise a splint from any handy piece of wood or fence. The plaster-of-paris slab echnique should also be taught, though this will scarcely f ever be of value on the actual field Every man should carry a thick piece of cord attached to his mackintosh-ape ground-sheet, and should be shown how to use the ord as a tourniquet, or failing that his roller bandage or first-field dressing At present each man has only one ield dressing and therefore cannot open it, and he cannot ee what it is or learn how to apply it unless one man in the class sacrifices his dressing In most instances it is he medical officer who has already done this and he has now no sterile first-field dressing No dressings have been issued for carrying on to the field for the adequate covering of burns, for this description can hardly apply to one or two small tubes of tannic-acid jelly, or to a small supply of anti-gas ointment No morphia is included in the official issue

Only a very small proportion of members of the Home Guard will be trained as stretcher-bearers, so that each man will have to help his friend as best he can and after applying a dressing or tourniquet to the best of his ability with the meagre medical supplies at present available he must then hide him in a ditch or thicket and all comrades must be told where he is, or if several are wounded an unwounded man must be left behind to care for them until the heat of battle moves on If by good chance a few stretcher-bearers happen to be where the casualties occur they will transfer them with all possible speed to the nearest available casualty collecting post Otherwise two of the wounded man's friends will have to carry him when their combatant services can be spared In the absence of a stretcher a gate or hurdle, or even a stretcher improvised from two rifles and a greatcoat will have to suffice In the event of only one man in a post being left unwounded, he will have to go to the nearest casualty collecting post where a stretcher must be available, and will take it back with him together with a civilian to bring in the wounded If a farm cart or wheelbarrow can be obtained so much the better

In addition to the subjects indicated an elementary knowledge of which should be thoroughly instilled into each Home Guardman he should also be given at least the same immunity treatment as is granted to regular troops Main water-supply is likely to be damaged over a wide area, and well or pump water, already or rapidly contaminated, would have to be used Every Home Guardman should be given an injection of T A.B T C — an injection which gives immunity from typhoid fever, both varieties of paratyphoid fever, tetanus and cholera. Since it is on members of the Home Guard that the first brunt of air-borne invasion will fall, they would be well advised to have this preventive treatment forthwith

ESTABLISHMENT OF CASUALTY COLLECTING POSTS

The name " casualty collecting post," which was introduced by Dr Gordon Ward, is self-explanatory, and is not to be confused with a regimental aid-post from which it differs in several respects A Home Guard casualty collecting post may be either (*a*) a separate entity not associated with any other organisation, or (*b*) an already established A R P first-aid post or point, E M S hospital, R A M C unit, fever hospital, &c The majority of such already existing arrangements are situated in or close to large towns, small towns or larger villages, and in these districts few Home Guard casualty collecting posts need be established It is important, however, that members of the Home Guard operating in these areas should be fully aware of the position of such facilities and that their services are available for their use if wounded, equally with wounded non-combatants Primary Home Guard casualty collecting posts will therefore usually be established in the more isolated or country districts

Great Britain measures approximately 100 000 square miles, and to judge from my district about half the total area is already equipped via A R P, E M S and R A M C, leaving approximately half which has to be organised with collecting posts, so that some 50 000 posts are required My posts have cost somewhat less than £10 each to equip (almost all raised voluntarily and mainly through the generosity of the Canadian Red Cross), and will probably reach that figure when we have sufficient palliasses, pillows and so on Is half a million pounds spent once and once only, for the medical care of Home Guard and other casualties a large sum out of a war expenditure of fourteen million pounds daily ? Bear in mind that if invasion does not come to your district these goods will still be usable and of value, so that even the half million pounds will not be wasted

In the county with which I am associated the object has been to arrange for a Home Guard casualty collecting post to be established at intervals of not more than one mile To this scheme of ours the War Office has imitation were necessary for the patients, and in sick-ays taking scabies cases a separate bathroom for these as desirable The surgery serving also as examination-oom and dispensary was usually on the ground floor, nd in some a minor-ailments clinic for evacuees was held n isolation-room for the segregation of suspected cases f infectious disease was also provided As the children ere usually only confined to bed for a small part of eir stay, where there was no separate playroom it was ecessary to have a dining-room which could also serve s one Facilities for outdoor recreation were provided herever possible

PERSONNEL

The number of beds in each sick-bay determined the umber of nursing staff to be employed At least one, nd usually two or more, state-registered nurses were nployed, the rest of the staff being assistant or auxiliary urses Many nurses working in these units were ecruited from the Civil Nursing Reserve and were paid t the appropriate rates Members of the British Red ross Society and St John Ambulance Brigade also erved, and both nursing and domestic staffs were upplemented by voluntary workers The cases treated d not need elaborate equipment The usual sources f equipment were central and regional Government ores, supplemented by local purchase where necessary

The clinical care of the children was undertaken by cal general practitioners, and one practitioner was sually nominated by the local medical war committee r this purpose, for it was generally preferable for one octor to take charge of the treatment of all cases, more articularly where patients were sent in from a distance his doctor also controlled admissions and discharges. ayment for this clinical care for unaccompanied hildren was made through the pool administered by the cal medical war committee, and a fee of 7*s* 6*d* per uarter was paid for each accompanied child, the parent ontributing as much as could be afforded In one or wo instances, the doctor was paid a retaining fee for eneral administration on behalf of the medical officer f health, but as a rule the local M O H took charge of e administrative arrangements himself

The county medical officer acted as coordinator for e sick-bay accommodation within his county, and by eans of a system of weekly returns it was possible to orrelate all the sick-bays in the region This regional orrelation proved in practice to be extremely useful, r when sick-bay accommodation in one county was eriously depleted by an outbreak of infectious disease hildren were transferred without difficulty to sick-bays adjoining counties Similarly, a sick-bay set aside one county for cases of scabies could serve adjoining ounties Consultants were rarely required for the minor lments admitted Patients who became seriously ill ere transferred to hospital, but it was occasionally ecessary to call on the services of a general physician or n ear, nose and throat surgeon

NALYSIS OF WEEKLY RETURNS OF 3279 CASES ADMITTED BETWEEN NOV 25, 1939, AND FEB 25, 1941

kin conditions—	
Scabies	886
Impetigo and septic sores	806

Births, Marriages and Deaths

BIRTHS

DIXON —On Sept 8, the wife of Dr J H Dixon of Braintree—a daughter

ELLIOTT —On Sept 13, at Windsor, the wife of Dr Frank Abercrombie Elliott—a daughter

GREEN —On Sept 11, at Guildford, the wife of Mr Anthony Green, F R C S —a daughter

MACLURE —On Aug 30, at Stourport, the wife of Dr Hugh Maclure, of Sierra Leone—a son

NAISH —On Sept 8, in Edinburgh, the wife of Surgeon Lieutenant John Naish, R N V R —a son

POOLE WILSON —On Sept 7, at Ascot, Berks, to the wife of Major D S Poole Wilson, R A M C —a son

ROSS —On Sept 8 at Northampton, the wife of Captain James Ross, R A.M C —a daughter

WALKER —On Sept 12, at Loughton, the wife of Dr Hugh Walker—a son

MARRIAGES

SMITH—SMITH —On Sept 6 at Pembridge, Richard William Smith, M.B , surgeon lieutenant R N V R , to Elsie Phœbe Valentine, Smith

DEATHS

ELKINS —On Sept 10, at Watford, Frank Ashby Elkins, M.D Edin , aged 79

SLOAN —On Sept. 10, at Ifield Sussex, John Macfarlane Sloan C.B , C M G , D S O , M B Glasg , major general late R.A M C.

HOME GUARD MEDICAL ARRANGEMENTS

A LAWRENCE ABEL, M S Lond , F R C S
GROUP MEDICAL OFFICER, HOME GUARD

WE are reminded almost every day, and always by the Prime Minister when he speaks to us, that invasion of this island is a virtual certainty That this will be carried out mainly by air-borne troops is almost equally certain That these troops may land in considerable numbers and at several different points is shown by the experience of other countries The landing of a large number of paratroops (120,000 fully equipped and armed men in six or eight widely separated districts is considered feasible) would be more likely to occur in isolated country districts than in the centre of a town In town districts the already established, well-equipped and well-staffed A R P. and other medical services are capable of dealing with casualties among both civilians and Home Guard men, but both civilians and combatants in country districts might be quite cut off from such aid, both in the immediate vicinity of hostilities and perhaps for several miles around My remarks therefore apply mainly to rural districts, though it must be borne in mind that even in towns severe damage may render even street to street communication impossible In any case, in a town the hospitals and first-aid posts are usually conspicuous buildings and likely to be easy and early targets and might soon be out of commission Therefore peripheral casualty collecting posts with adequate cellars should not be neglected in urban districts

It may be estimated that among any particular platoon of Home Guard men as many as 90% might be casualties within a few hours of the arrival of the air-borne force Wise as it may be therefore to have a number of trained stretcher-bearers every member of the Home Guard should be taught as much first-aid as is possible in the small time at our disposal, in order that each man may be able to help his pal It should be remembered that every member of the Home Guard, except a medical officer wearing a red cross brassard, is a combatant who has no Home Guard Medical Corps to come to his aid Each Home Guardman therefore stands an equal chance of being wounded, and by the same token an equal chance of being called on to carry out first-aid for his friend

The Home Guard Medical Service should be responsible for first-aid training and for treatment before hostilities The former will result in reasonable care of the wounded at the time of injury They should also be responsible for the establishment, staffing and equipping of casualty collecting posts in rural and sometimes urban districts, where A R P or other facilities cannot be relied on If both these functions are carried out it follows that arrangements will be organised for the transport of casualties from the battlefield to the collecting post, and for their care there for an indefinite period

FIRST-AID TRAINING AND IMMUNISATION

Each commanding officer should arrange that his medical officer should be given every facility to impart, and that every man in his battalion should attend to receive, instruction in simple first-aid This should be with special reference to the treatment of wounds, including fractures and hæmorrhage of burns and of pain Every man should be made to carry an 18 ft by 3 in roller bandage together with his first-field dressing, and should be taught how to improvise a splint from any handy piece of wood or fence The plaster-of-paris slab technique should also be taught, though this will scarcely if ever be of value on the actual field Every man should carry a thick piece of cord attached to his mackintosh-cape ground-sheet, and should be shown how to use the cord as a tourniquet, or failing that his roller bandage or first-field dressing At present each man has only one field dressing and therefore cannot open it, and he cannot see what it is or learn how to apply it unless one man in the class sacrifices his dressing In most instances it is the medical officer who has already done this, and he has now no sterile first-field dressing No dressings have been issued for carrying on to the field for the adequate covering of burns, for this description can hardly apply to one or two small tubes of tannic-acid jelly, or to a small supply of anti-gas ointment No morphia is included in the official issue

Only a very small proportion of members of the Home Guard will be trained as stretcher-bearers, so that each man will have to help his friend as best he can, and after applying a dressing or tourniquet to the best of his ability with the meagre medical supplies at present available he must then hide him in a ditch or thicket and all comrades must be told where he is, or if several are wounded an unwounded man must be left behind to care for them until the heat of battle moves on If by good chance a few stretcher-bearers happen to be where the casualties occur they will transfer them with all possible speed to the nearest available casualty collecting post Otherwise two of the wounded man's friends will have to carry him when their combatant services can be spared In the absence of a stretcher, a gate or hurdle, or even a stretcher improvised from two rifles and a greatcoat will have to suffice In the event of only one man in a post being left unwounded, he will have to go to the nearest casualty collecting post where a stretcher must be available, and will take it back with him together with a civilian to bring in the wounded If a farm cart or wheelbarrow can be obtained so much the better

In addition to the subjects indicated, an elementary knowledge of which should be thoroughly instilled into each Home Guardman, he should also be given at least the same immunity treatment as is granted to regular troops Main water-supply is likely to be damaged over a wide area, and well or pump water, already or rapidly contaminated, would have to be used Every Home Guardman should be given an injection of T A B T C — an injection which gives immunity from typhoid fever, both varieties of paratyphoid fever, tetanus and cholera Since it is on members of the Home Guard that the first brunt of air-borne invasion will fall, they would be well advised to have this preventive treatment forthwith

ESTABLISHMENT OF CASUALTY COLLECTING POSTS

The name " casualty collecting post," which was introduced by Dr Gordon Ward, is self-explanatory, and is not to be confused with a regimental aid-post from which it differs in several respects A Home Guard casualty collecting post may be either (*a*) a separate entity not associated with any other organisation, or (*b*) an already established A R P first-aid post or point, E M S hospital, R A M C unit, fever hospital, &c The majority of such already existing arrangements are situated in or close to large towns, small towns or larger villages, and in these districts few Home Guard casualty collecting posts need be established It is important, however, that members of the Home Guard operating in these areas should be fully aware of the position of such facilities and that their services are available for their use if wounded, equally with wounded non-combatants Primary Home Guard casualty collecting posts will therefore usually be established in the more isolated or country districts

Great Britain measures approximately 100 000 square miles, and to judge from my district about half the total area is already equipped via A R P , E M S and R A M C , leaving approximately half which has to be organised with collecting posts , so that some 50,000 posts are required My posts have cost somewhat less than £10 each to equip (almost all raised voluntarily and mainly through the generosity of the Canadian Red Cross), and will probably reach that figure when we have sufficient palliasses, pillows and so on Is half a million pounds spent once, and once only, for the medical care of Home Guard and other casualties a large sum out of a war expenditure of fourteen million pounds daily ? Bear in mind that if invasion does not come to your district these goods will still be usable and of value, so that even the half million pounds will not be wasted

In the county with which I am associated the object has been to arrange for a Home Guard casualty collecting post to be established at intervals of not more than one mile To this scheme of ours the War Office has given its full approval From this it follows that no wounded man will have to walk, crawl or be carried more than half a mile and will always have four available posts within a mile of him * The suggestion has been made that every house in the neighbourhood of the battle could give shelter to a wounded man, but it follows that when it is possible for a medical man to reach the region he will have no idea where to go nor will he find equipment available nor will the best house or the one with the best cellar and most efficient local nurse be utilised Collection will have been made before the roads become available for ambulances, and the idea we had in mind in forming these posts—to avoid casualties being scattered or lost, to have them already collected and in readiness for further transport with the least possible delay, to provide the maximum care and treatment until that happens—would be nullified THE LANCET leader of Aug 16 points out the difficulty of transmitting messages or aid The idea which "H G M O" puts forward (*Lancet*, 1941, 2, 268), of a runner armed to the teeth with splints, dressings, bandages, tourniquets, morphia, anti-tetanus serum and tins of Vaseline gauze scuttling in the darkness along unfrequented by-paths and beside treacherous hedgerows through the enemy-infested countryside, smelling out the wounded (probably the best way of finding 'em *by that time), each in an isolated cottage, administering* first-aid by candle light and coping with the frightened and unprepared inhabitants, and then hurrying on again unscathed through the night, would be laughable if it were not pathetic

Selection of posts —The battalion medical officer should be a local practitioner who knows his battalion area well Not only does he know the suitability or otherwise of most of the houses in his district, but he also knows the inhabitants of those houses A consideration of these two factors will lead him to choose his posts to the greatest advantage From this it follows that municipal employees, who obviously lack this special knowledge, will be unlikely to choose the best posts A private house or farmhouse or schoolroom or inn will be chosen because of its facilities of space light, heat, water, if possible with adequate cellar accommodation The latter is important, for if no cellars are available hand grenades may be thrown in at the window by the enemy and cause havoc among the wounded—not only the wounded Home Guardmen, but also wounded civilians who will have gathered there, and unwounded personnel who may be attending to them If adequate cellar accommodation is available, care of the wounded may be carried on with much less interruption than will be likely in a groundfloor room In addition, the suitability of the housewife and her associates for caring for the sick will be taken into consideration The majority of our posts are fortunate in having the services of a nurse, ex-nurse or midwife, or someone who has had considerable if not large, nursing experience Great help in the selection of posts has been given by the company medical officers, many of whom are practitioners who know their own district intimately

Label —A large notice with the letters H G and a red cross should be exhibited in a conspicuous position outside each Home Guard casualty collecting post A list of posts should be in each company and battalion headquarters, and commanding officers and platoon officers should make certain that all ranks are aware of their nearest casualty collecting posts

EQUIPMENT OF POSTS

If each post is well chosen simple equipment will already be found there—bowls towels, soap and water, and a bottle of antiseptic (the latter is probably quite unnecessary, but tradition dies hard, and the lay first-aider seems lost without something that smells of carbolic or colours the water) More important equipment is not so easy to come by In addition to the meagre army supply to the Home Guard, we have aimed at having the following in each casualty collecting post, and have obtained voluntary help to provide nearly all of it 10–15 roller bandages (3 in or 4 in), 5–10 T-bandages , 15–20 triangular bandages Adequate supplies of these types of bandages are apparently in the country The great difficulty appears to be to get the local Red Cross for a county or district to realise that they are of no value in a central depot, which might be quite cut off from the wounded needing them in time of invasion, and that they had better be dispersed in small numbers to equip four posts to every square mile of the country If this cannot be done, local ladies' sewing parties, Church sewing parties and Women's Voluntary Services must be approached, and it has been found that the local medical man seldom has difficulty in obtaining an adequate supply from these generous and ardent sources at short notice

I agree with Mr V B Green-Armitage (*Lancet*, 1941, 2 230) that it is unfair that medical officers of battalions should go round cap in hand asking for donations, but since neither the state nor the British Red Cross, with all their voluntary supplies from the American Red Cross, will do much to help us other funds must be obtained I suggest that the medical officer in his lectures should appeal to all members of the Home Guard that the urgent medical necessities are for each and every man's use, and that donations should be blatantly asked for both from Home Guard themselves and those whom they are about to defend In my experience it is almost useless to approach any established organisation for supplies , the Red Cross has become so exsanguinated by red tape as to be almost invisible on its white back ground *Of course every platoon of every company of* every battalion should be provided with urgent medical necessities, but where is the Houdini who can rescue us from the red-tape entanglements ?

Fresh clothing —Many of the casualties reporting at a Home Guard collecting post will be wet or have their clothing ruined by mud, blood or rending We have therefore aimed at having two or three pairs of pyjamas, two or three pneumonia jackets, three or four bed gowns and five or six pairs of socks available at each post These will sometimes be voluntarily loaned by the owner of the house in which the post is situated, or the lady of the house herself may collect from her friends such articles which would usually go to the jumble sale Thus an adequate supply will always be available

Bedding —In the type of house we have indicated five or six blankets will almost always be available for the wounded, but in addition to those we have also provided five or six blankets for each post by voluntary effort from outside sources It is therefore worth while appealing to local voluntary effort for the loan or donation of blankets so that each post has a few for the sole use of casualties Each such loaned blanket can be labelled with the owner's name and address, and claimed and returned when no longer required Very few posts have the means of providing beds or mattresses for 10–20 wounded men, let alone wounded women and children who are also likely to forgather there, and although there is little doubt that the ordinary occupiers of a house will have no time to sleep in their own beds when casualties begin to arrive, yet some extra provision than their own mattresses should be made available for the wounded A house-to-house collection of old sheets must be made, and local voluntary sewing parties must sew them into sacks (7–8 ft long by 2 ft 6 in. wide), and they must be stuffed with dry straw, bracken, chaff or rags, and kept in a dry place From the odd pieces of cotton or linen which are left over pillows must be made and stuffed with dry grass

Food —The local controller should be approached immediately and a tinned supply of iron ration provided for each post and kept hidden

Drugs —Each of my posts has ten grains of morphine supplied as 30 tablets, each containing gr $\frac{1}{3}$, for placing under the tongue, a small bottle with gauze cover and screw-on cap containing an ounce of sulphanilamide powder, and a sterile tin with 9 ft by 6 in Vaseline gauze These are kept under lock and key Most of my equipment has been provided by the C R C , but local friends have paid for most of the drugs, which have been supplied at most reasonable prices by Messrs John Bell and Croyden

Light —A supply of candles should be kept near the dressings, but a hurricane lamp would be better

Instructions —Simple printed instructions should be given with each parcel or packing case of Home Guard dressings The following (slightly modified) were drawn up by Dr J W Cannon, and printed and distributed by him

---

* I should like to record the valuable and energetic work carried out in this connexion by Dr H Stratford Collins Dr J W Cannon and Dr R G Birch

FIRST-AID TREATMENT OF THE WOUNDED

Relieve pain —Handle and transport the patient carefully Make the patient comfortable In the case of chest or abdominal wounds place in a half sitting position If pain is severe place one tablet (⅓rd grain) of morphine under the tongue (the tablet is absorbed there and is not swallowed) A second dose may be given if necessary in half an hour No further dose should be given for about 4 hours

The wound —1 Arrest hæmorrhage by firm pressure bandaging over a dry ("first aid") dressing This method is nearly always effective, though finger pressure over the artery or even a tourniquet may be necessary 2 Sprinkle sulphanilamide powder freely on the wound 3 Apply a dry ("first-aid") dressing and a bandage (Splint severe wounds of the limbs)

Burns (*not* applicable to effects of blister gas) —1 Sprinkle sulphanilamide powder freely on the burnt area 2 Cover the burnt area with Vaseline gauze 3 Cover with a layer of cotton wool 4 Apply a bandage

Fractures of the limbs should be splinted immediately ("splint 'em where they lie") to secure immobility of the fractured bone and limb Treat any wound as described above

Provide warmth —Replace wet and dirty clothes with dry ones Protect from cold by blankets under as well as over the patient

Keep the room warm and the bed heated by hot water bottles or hot bricks covered with flannel Raise the foot of the bed or stretcher on blocks about 12 in high

Give fluids (except in the case of abdominal wounds) — Water or any beverage Hot sweetened tea or coffee is best Add half a teaspoonful of common salt to each pint of fluid Insist on fluids being taken

Clearness of vision and adequate preparation *now* will lead to the saving of life and suffering amongst Home Guardmen Our posts thus prepared and equipped will not only serve to hearten the combatants but will help to stabilise the civilian population in any area attacked Let us therefore carry out the War Office instructions, let us do the job thoroughly, but let us do it now

---

MIDDLE-CLASS DIETS IN PEACE AND WAR

E M WIDDOWSON, B SC, PH D
B K ALINGTON, B A

(*Department of Medicine, Cambridge*)

DURING the first four months of the war McCance and Widdowson carried out an experimental study of rationing Eight people were given a diet in which fat, meat, bacon, sugar, jam and milk were more severely restricted than they are at the present time, but in which bread, potatoes and other vegetables were freely available They showed that healthy active people did not allow these restrictions permanently to curtail their calorie intakes More and more bread and potatoes were eaten, until the calories were as high as they had been before the restrictions were imposed McCance and Widdowson predicted that if rationing became widespread and severe the demand for bread and potatoes would increase, and that, if most other foods were rationed, a forecast could be made of what those increases would be They also found that the appetising and tasty functions of the rationed foods tended to be replaced by the judicious use of other unrationed flavourings They emphasised the value of adjuvants such as onions, curry and chutneys to restricted diets They established a general principle which seems to underlie all systems of rationing—that as one food becomes scarce it tends to be replaced by another This applies both to foods which are of calorific value and to foods which are eaten especially for some piquant flavour

In March, 1941, foodstuffs could be divided into three categories There were those that were officially rationed These included butter, margarine and cooking fat, cheese, meat, bacon, jam and tea There were those which were officially unrationed, but were difficult to obtain, or very expensive, or both Fruit, fish, sausages and "cooked meat," cakes, biscuits, sweets and chocolate fell into this group Milk was officially restricted to ⅔ of its previous level, and eggs were readily available only for one or two weeks Lastly, there were some foods such as bread and potatoes which were plentiful and cheap Green vegetables and carrots were also fairly abundant By the spring of this year, therefore, it was evident that 18 months of war must have forced many people to alter their established dietary practices, and it seemed very desirable to have some information on these matters To what extent were the rations really restrictions? Was the apparent scarcity of an unrationed food due to increased demand or to decreased supply? If the consumption of some commodities was curtailed, were people eating less food, or were they turning to other, more plentiful foods?

TABLE I—COMPARISON OF GROUPS OF WOMEN INVESTIGATED IN 1935 AND 1941

	1935	1941
Number of women	63	57
Average age in years	32 5	39
Average weight in lb (indoor clothes and shoes)	135	130 3
Average height in ins (no shoes)	64 1	63 7
Occupations—		
Housewives	17	27
Students	15	10
Secretaries, clerks, &c	11	2
Teachers	7	6
Research workers	3	7
Miscellaneous	10	5
Living in large towns or cities	57	47
Living in small towns	4	4
Living in country	2	6

In 1935 Widdowson, and Widdowson and McCance carried out dietary surveys by the individual method on 63 men and 63 women of the English middle class Records were obtained of the diet of each of these persons over a period of one week By re-analysing this data it has been possible to compare the food eaten in 1935 with the rations in 1941 Further, by making another dietary survey in the spring of 1941 it has been possible to get some insight into all the dietary changes which had taken place The 1941 survey was carried out on 57 individual women, who were chosen to be as similar as possible to those in the original investigations Relevant details are given in table I The same method was used as before, and need not be described again This survey was made during March, April, and May, 1941 The original one was carried out during the period November, 1934–July, 1935 Seven of the subjects who took part in the first investigation also participated in the second

Both these surveys on women have been limited to a particular social class because naturally no comparison would have been valid unless the two groups were similar Further, some of the results may not be true of the country as a whole Many of the findings, however, are certainly of general application One other point the 1935 survey was carried out 4½ years before the outbreak of war An increase in the popularity of a foodstuff between 1935 and 1939 may have masked a decrease in consumption due to war-time restrictions

RATIONED FOODS

Table II shows the rations in force in spring 1941, and the quantities of the rationed foods eaten by the men and women in the 1935 survey It also shows the amounts eaten by the women in the 1941 survey Certain assumptions have had to be made in compiling this data from the dietary records, particularly as regards cooked dishes As a general ruling it has been assumed that all puddings, stewed fruit and savoury dishes were prepared at home out of raw ingredients, but that cakes, biscuits and tinned fruit were purchased as such Allowance has been made for the fact that recipes demanding less fat and sugar were being used in the 1941 survey

It will be seen that the rationing system must have cut right across the dietary habits of the men The women, at any rate of this particular social group, *have been* much less affected because they were not in the habit of eating so much of the rationed foods before the war Nevertheless, the ration of almost every commodity, for women as well as men, was less than their prewar intake

TABLE II—AVERAGE INTAKES OF RATIONED FOODS IN 1935 AND 1941 COMPARED WITH RATIONS IN SPRING 1941 (OZ PER WEEK)

—	1935		1941	
	Men	Women	Women	Ration
Butter	11 7	9 8	3 7	4
Cheese	4 9	2 9	1 3	1
Sugar	16 7	7 4	4 5	8
Jam	5 7	4	5 8	2
Rationed meat (raw weight)	34 5	19 7	11 4	about 12 (1*s* worth)
Bacon (raw weight)	10 2	4 4	3 9	4

Figs 1–3 show the frequency with which different amounts of the rationed foods were eaten The hatched portion represents intakes within the ration

Fat —In spring 1941 the total fat ration was 8 oz a week Of this, 4 oz could be purchased as butter, 2 oz as margarine, and 2 oz as lard or lard substitute If the customer preferred, she could replace part or all of the butter or lard with margarine Suet and dripping were not rationed It has been found impossible to arrive at any accurate figure for the amount of rationed cooking fat used by the women taking part in these surveys There was no way of telling what proportion of the cakes and biscuits had been home-made, and even if it was assumed that they had all been bought in shops there was still no clue as to whether puddings had been made with rationed or unrationed cooking fat Taking all types of cooking fat into account the women's consumption averaged about 5 oz per week in 1935 and the same amount in 1941 The amount of butter used with bread was stated on the records, so this can be given with some measure of confidence Both men and women in the 1935 survey were eating an average of 2–3 times as much butter as they were allowed in spring 1941 Only 6 of the men and 4 of the women ate 4 oz a week or less More than half the men were eating 8–16 oz and ⅔ of the women between 4 and 12 oz In the 1941 survey the average amount eaten was very close to the ration , 44 of the women were eating less and 13 more than their rightful allowance In the 1941 survey 25 of the women ate margarine on bread and the average amount eaten in this way was 1 oz a week , nobody ate margarine on bread in the prewar study

Cheese —All cheese used in cooked dishes is included under this heading In the 1935 survey the amounts of cheese eaten by the individuals varied widely , 5 men and 11 women ate none , 5 men and 1 woman ate more than 12 oz during the week The men's intakes averaged 5 oz and the women's 3 oz a week A weekly ration of 1 oz became operative in May, 1941, when the second survey was nearly over, so only a small proportion of the women taking part in this investigation were affected by it Cheese had, however, been difficult to obtain before official rationing began, and the average amount eaten in the 1941 survey was very little more than 1 oz a week , 33 of the women ate amounts that were within this ration , 12 ate none at all

Sugar and jam —The 1941 jam ration of 2 oz a week would have sufficed for about a third of the men and women in the 1935 survey, but the average consumption at that time was 2–3 times the official ration of 1941 Surprising though it may sound, 50 out of the 57 women in the 1941 survey were exceeding their ration of jam, and their average consumption was nearly 3 times their official allowance They could only have managed this if they had had stores of jam laid by The desire for jam might have been expected from McCance and Widdowson's experimental study of rationing The people in that investigation had an all-in allowance of *5 oz of sugar per week* They always chose to have the whole of it issued to them in the form of jam, which they spread out thinly over large quantities of bread In spring 1941 conditions were not nearly so stringent as the experimental ones, but butter was relatively scarce, as were many of the other relishes so easily obtained before the war Hence the women in the 1941 survey felt the need for jam, and they drew on their reserves to satisfy it What are they going to do when their stocks are exhausted? Some will adopt alternative flavouring agents, but the figures for sugar suggest that many will continue to eat jam

In spring 1941 the women were eating an average of little more than half their sugar ration taking into account sugar in stewed and home-bottled fruit and puddings as well as sugar recorded as such Only 4 women ate more than 8 oz a week from these sources A reserve of sugar was evidently being built up for jam-making in the 1941 fruit season Of course, the men in the household may have been eating some of the women's sugar ration In the 1935 survey, before any rationing was imposed, the men ate 2–3 times as much sugar as the women, and it seems likely that they may now be getting the lion's share of the family ration

It must be remembered, however, that there are several foods in everyday use, other than those already mentioned, which contain commercial cane sugar These are usually purchased ready made, and hence the sugar they contain is an extra to the official ration Cakes and biscuits contributed about 3 oz of sugar a week to the 1935 and 2 5 oz to the 1941 diets Tinned fruit contributed 0 2 oz on both occasions Jam provided 2 7 oz in 1935 and 3 9 oz in 1941 Sweets and chocolates contributed 2 6 and 1 3 oz in the 1935 and 1941 surveys respectively Hence, taking all sources into account, the women were eating about 15 9 oz of cane sugar a week in 1935 and 12 4 oz in 1941 This figure will fall to 10 9 oz when the stocks of jam are exhausted and the women are reduced to their jam and sugar rations

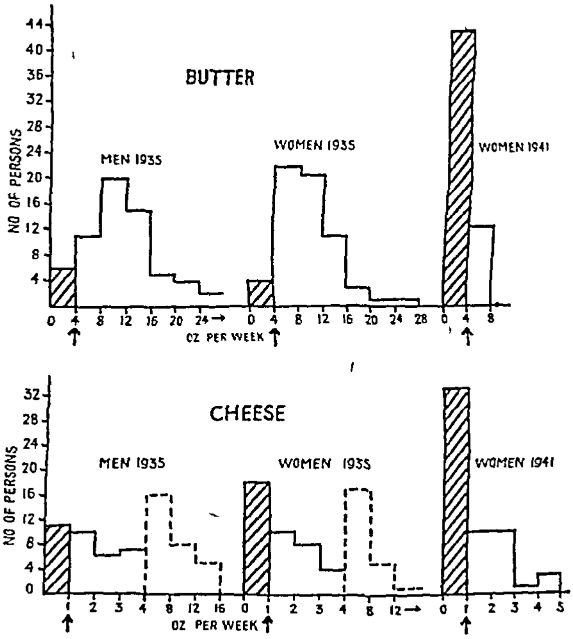

FIG 1—Frequency distribution of butter and cheese intakes Arrows indicate ration in spring 1941 and shaded areas intakes within that ration

Meat —The figures for meat include all meat that was rationed in March, 1941—i e , all butcher's meat and offal, but not poultry, rabbits, sausages, ham or “ cooked meat ” in pies, &c Only 2 out of the 63 men in the 1935 survey were within their 1941 meat ration Most of them were eating between 12 and 36 oz a week, and 22 of them recorded more than 36 oz Their average intake was about 3 times as much as their ration in 1941 The women in 1935 ate little more than half as much meat as the men , this, however, was considerably more than their 1941 allowance The average intake in 1941 was 11 4 oz and the maximum 23 oz In 1935, 17 of the women were eating more than the latter amount

Bacon —The rationing of bacon to 4 oz a week hardly seems to have affected women's consumption of this food, for in the 1935 survey they were eating little more than this amount, and not much less in 1941 For men, however, this ration was more of a privation , it must have reduced their intake to two-fifths of its prewar level

RESTRICTED FOODS

By comparing the data obtained from the surveys of 1935 and 1941 it has been possible to gain some idea as to how far the difficulty of procuring some foods has affected their consumption

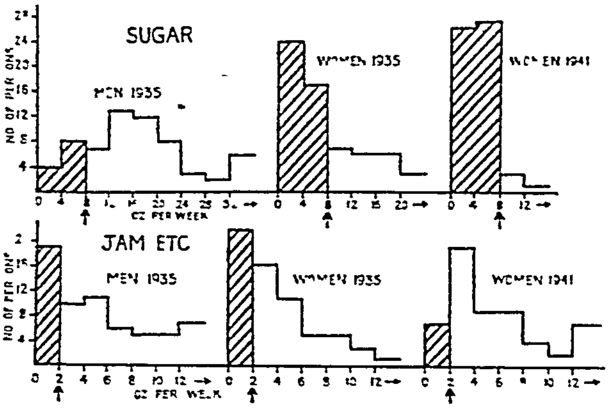

FIG 2—Frequency distribution of sugar and jam intakes

Fruit —Table III shows that in 1935 the women were eating an average of 29 1 oz of raw fruit a week, or over 4 oz a day Apples and pears made up half of this, oranges and bananas the remainder Of course small amounts of other fruits were also eaten Tomatoes are not included here as they have been given separately Of the 63 women 3 ate no raw fruit of any kind during the week of investigation In spring 1941 raw fruit had almost disappeared from the market Then, 6 women ate apple, one of them 15 oz , one woman had a little orange in a jelly , 50 had no raw fruit at all, and the per-caput consumption was a mere 0 6 oz

The rise in consumption of so-called cooked fruit, with which is included home-bottled fruit, may sound surprising It is due to several causes First, the 1941 survey was carried out at the height of the rhubarb season, and this garden product accounted for over half the "stewed fruit" Second it is probable that more fruit was bottled at home in 1940 than in the prewar years Third a consignment of dried apple rings from Canada during the winter 1940–41 provided fruit for cooking during the early months of 1941 Fourth, the provision of puddings is now a problem for the housewife She tends to turn more frequently to stewed fruit, which, with the aid of saccharin and sodium bicarbonate, she can prepare with a minimum of sugar

The consumption of tinned fruit was much the same in 1941 as it had been in 1935 One woman, who ate 36 oz in the week has been excluded from the 1941 average About a third of the women in the 1935 survey and a quarter of them in 1941 had some tinned fruit The restriction in supplies of dried fruit (raisins, sultanas, currants, dates) in 1941 is not very obvious from table III One woman in the 1935 group, who ate 18 oz dates during the week has been excluded from the average

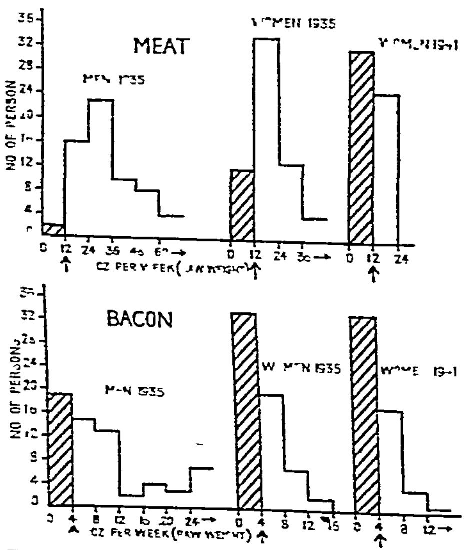

FIG 3—Frequency distribution of meat and bacon intakes

Only one woman ate any tomato in the 1941 survey, and she had a very small amount In 1935 the intakes averaged nearly 5 oz a week, and ranged from none to 38 oz Neither survey covered the season when raw salads were abundant, and the intakes were equally low in 1935 and 1941

Meat —The average consumption of unrationed meat fell as indeed would be expected On both occasions it consisted chiefly of sausages and meat bought ready cooked Allowance has been made for the smaller amount of meat in war-time sausages

Fish —In 1941 the average intake of fresh and dried fish was less than half what it had been in 1935 Increased price was probably the chief reason for this Supplies were undoubtedly less, but the greater cost led to a decreased demand Hence there was not much apparent shortage Of the women in 1941, 30 partook of some form of tinned fish, the supplies of which were still ample at that time In 1935, when other foods were cheap and easy to obtain, only 12 of the women seem to have been attracted by this kind of fish and the per-caput consumption was only ¼ as great

Eggs —Both the 1935 and 1941 surveys covered the season of the year when eggs were relatively plentiful Although the number of eggs eaten was less in the 1941 survey, there is no doubt that the difference would have been much greater had the survey been made at another season of the year Before the war there were plentiful supplies of imported eggs during the winter months

TABLE III—AVERAGE INTAKES OF RESTRICTED FOODS IN 1935 AND 1941 (OZ. PER WEEK)

		Women 1935	Women 1941
Fruit	raw	29 1	0 6
	cooked (excluding sugar)	7 5	11 4
	tinned	1 7	1 5
	dried	1 1	0 8
Tomato, raw and cooked		4 9	0
Raw salad (excluding tomato)		2 5	2 5
Unrationed meat (raw weight)		7 4	4 7
Fish	fresh and dried (raw weight)	9 3	4 0
	tinned	0 4	1 1
Eggs (number)		4 2	3 2
Cream		1 7	0
Cake		11 5	11 7
Biscuits		3 2	5 0
Sweets and chocolates		3 9	1 9
Milk (pints)		3 3	4 6

Cream —In the 1935 survey more than two-thirds of the women had some cream during the week of investigation, and the average consumption was 1 7 oz a week In 1941 the sale of fresh cream was prohibited ; 3 of the women entered small amounts of cream on their records, but in each case it came out of a tin

Confectionery —The figures for cakes and biscuits justify rather more comment In spite of the apparent scarcity of cake and biscuits in the shops, the average consumption of cake was the same in 1941 as it had been in 1935, and the intake of biscuits had increased. The proportion of the cake which was home-made was likely to have been higher in 1935, when there were no restrictions on fat, sugar and eggs Now the housewife cannot make cake as she formerly did and she tries to buy it ready made Hence, the apparent scarcity is probably partly due to an increased demand The same applies to biscuits People who never bought biscuits before are undoubtedly buying them now As shopping becomes more difficult the housewife is only too glad to be able to get biscuits to make up for the fruit and sweets that she cannot now obtain These results are consistent with the fact that there has been an appreciable increase in the manufacture of cakes and biscuits since the prewar period, in spite of reduced allocations of fat and sugar The only biscuits now being made are the plainer varieties

The amount of sweets and chocolates eaten was about half as much in the 1941 survey as it had been in 1935 ; 14 of the 1935 group and 20 of those taking part in the

TABLE II—AVERAGE INTAKES OF RATIONED FOODS IN 1935 AND 1941 COMPARED WITH RATIONS IN SPRING 1941 (OZ PER WEEK)

—	1935		1941	
	Men	Women	Women	Ration
Butter	11 7	9 8	3 7	4
Cheese	4 9	2 9	1 3	1
Sugar	16 7	7 4	4 5	8
Jam	5 7	4	5 8	2
Rationed meat (raw weight)	34 5	19 7	11 4	about 12 (1s worth)
Bacon (raw weight)	10 2	4 4	3 9	4

Figs 1–3 show the frequency with which different amounts of the rationed foods were eaten The hatched portion represents intakes within the ration

Fat —In spring 1941 the total fat ration was 8 oz a week Of this 4 oz could be purchased as butter, 2 oz as margarine, and 2 oz as lard or lard substitute If the customer preferred, she could replace part or all of the butter or lard with margarine Suet and dripping were not rationed It has been found impossible to arrive at any accurate figure for the amount of rationed cooking fat used by the women taking part in these surveys There was no way of telling what proportion of the cakes and biscuits had been home-made, and even if it was assumed that they had all been bought in shops there was still no clue as to whether puddings had been made with rationed or unrationed cooking fat Taking all types of cooking fat into account the women's consumption averaged about 5 oz per week in 1935 and the same amount in 1941 The amount of butter used with bread was stated on the records, so this can be given with some measure of confidence Both men and women in the 1935 survey were eating an average of 2–3 times as much butter as they were allowed in spring 1941 Only 6 of the men and 4 of the women ate 4 oz a week or less More than half the men were eating 8–16 oz and ⅔ of the women between 4 and 12 oz In the 1941 survey the average amount eaten was very close to the ration , 44 of the women were eating less and 13 more than their rightful allowance In the 1941 survey 25 of the women ate margarine on bread and the average amount eaten in this way was 1 oz a week , nobody ate margarine on bread in the prewar study

Cheese —All cheese used in cooked dishes is included under this heading In the 1935 survey the amounts of cheese eaten by the individuals varied widely , 5 men and 11 women ate none , 5 men and 1 woman ate more than 12 oz during the week The men's intakes averaged 5 oz and the women's 3 oz a week A weekly ration of 1 oz became operative in May, 1941, when the second survey was nearly over, so only a small proportion of the women taking part in this investigation were affected by it Cheese had, however, been difficult to obtain before official rationing began, and the average amount eaten in the 1941 survey was very little more than 1 oz a week , 33 of the women ate amounts that were within this ration , 12 ate none at all

Sugar and jam —The 1941 jam ration of 2 oz a week would have sufficed for about a third of the men and women in the 1935 survey, but the average consumption at that time was 2–3 times the official ration of 1941 Surprising though it may sound, 50 out of the 57 women in the 1941 survey were exceeding their ration of jam, and their average consumption was nearly 3 times their official allowance They could only have managed this if they had had stores of jam laid by The desire for jam might have been expected from McCance and Widdowson's experimental study of rationing The people in that investigation had an all-in allowance of 5 oz of sugar per week They always chose to have the whole of it issued to them in the form of jam, which they spread out thinly over large quantities of bread In spring 1941 conditions were not nearly so stringent as the experimental ones, but butter was relatively scarce, as were many of the other relishes so easily obtained before the war Hence the women in the 1941 survey felt the need for jam, and they drew on their reserves to satisfy it What are they going to do when their stocks are exhausted ? Some will adopt alternative flavouring agents, but the figures for sugar suggest that many will continue to eat jam

In spring 1941 the women were eating an average of little more than half their sugar ration, taking into account sugar in stewed and home-bottled fruit and puddings as well as sugar recorded as such Only 4 women ate more than 8 oz a week from these sources A reserve of sugar was evidently being built up for jam-making in the 1941 fruit season Of course, the men in the household may have been eating some of the women's sugar ration In the 1935 survey, before any rationing was imposed, the men ate 2–3 times as much sugar as the women, and it seems likely that they may now be getting the lion's share of the family ration

It must be remembered, however, that there are several foods in everyday use, other than those already mentioned, which contain commercial cane sugar These are usually purchased ready made, and hence the sugar they contain is an extra to the official ration Cakes and biscuits contributed about 3 oz of sugar a week to the 1935 and 2 5 oz to the 1941 diets Tinned fruit contributed 0 2 oz on both occasions Jam provided 2 7 oz in 1935 and 3 9 oz in 1941 Sweets and chocolates contributed 2 6 and 1 3 oz in the 1935 and 1941 surveys respectively Hence, taking all sources into account, the women were eating about 15 9 oz of cane sugar a week in 1935 and 12 4 oz in 1941 This figure will fall to 10 9 oz when the stocks of jam are exhausted and the women are reduced to their jam and sugar rations

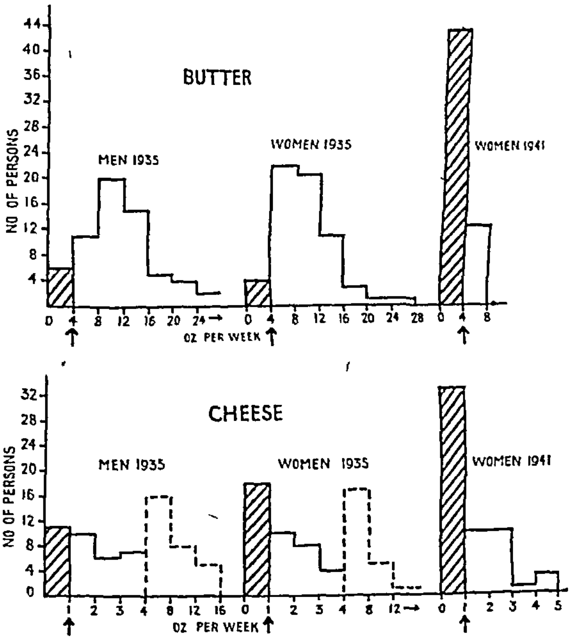

FIG 1—Frequency distribution of butter and cheese intakes Arrows indicate ration in spring 1941 and shaded areas intakes within that ration

Meat —The figures for meat include all meat that was rationed in March, 1941—i e , all butcher's meat and offal, but not poultry, rabbits, sausages, ham or " cooked meat " in pies, &c Only 2 out of the 63 men in the 1935 survey were within their 1941 meat ration Most of them were eating between 12 and 36 oz a week, and 22 of them recorded more than 36 oz Their average intake was about 3 times as much as their ration in 1941 The women in 1935 ate little more than half as much meat as the men , this, however, was considerably more than their 1941 allowance The average intake in 1941 was 11 4 oz and the maximum 23 oz In 1935, 17 of the women were eating more than the latter amount

Bacon —The rationing of bacon to 4 oz a week hardly seems to have affected women's consumption of this food, for in the 1935 survey they were eating little more than this amount, and not much less in 1941 For men, however, this ration was more of a privation, it must have reduced their intake to two-fifths of its prewar level

RESTRICTED FOODS

By comparing the data obtained from the surveys of 1935 and 1941 it has been possible to gain some idea as to how far the difficulty of procuring some foods has affected their consumption

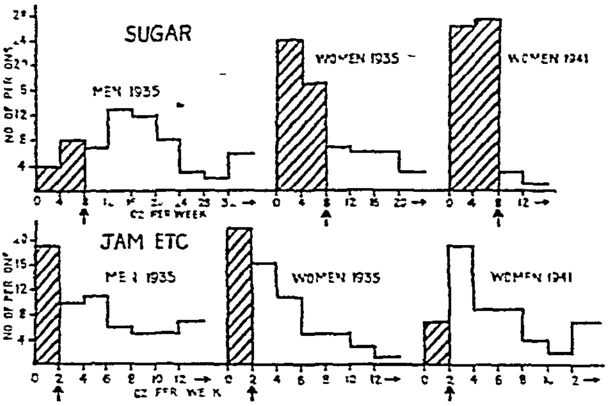

FIG 2—Frequency distribution of sugar and jam intakes

Fruit—Table III shows that in 1935 the women were eating an average of 29·1 oz of raw fruit a week, or over 4 oz a day Apples and pears made up half of this, oranges and bananas the remainder Of course small amounts of other fruits were also eaten Tomatoes are not included here as they have been given separately Of the 63 women 3 ate no raw fruit of any kind during the week of investigation In spring 1941 raw fruit had almost disappeared from the market Then, 6 women ate apple, one of them 15 oz , one woman had a little orange in a jelly , 50 had no raw fruit at all, and the per-caput consumption was a mere 0·6 oz

The rise in consumption of so-called cooked fruit, with which is included home-bottled fruit, may sound surprising It is due to several causes First, the 1941 survey was carried out at the height of the rhubarb season, and this garden product accounted for over half the "stewed fruit" Second it is probable that more fruit was bottled at home in 1940 than in the prewar years Third, a consignment of dried apple rings from Canada during the winter 1940–41 provided fruit for cooking during the early months of 1941 Fourth, the provision of puddings is now a problem for the housewife She tends to turn more frequently to stewed fruit, which, with the aid of saccharin and sodium bicarbonate, she can prepare with a minimum of sugar

The consumption of tinned fruit was much the same in 1941 as it had been in 1935 One woman who ate 36 oz in the week, has been excluded from the 1941 average About a third of the women in the 1935 survey and a quarter of them in 1941 had some tinned fruit The restriction in supplies of dried fruit (raisins, sultanas, currants, dates) in 1941 is not very obvious from table III. One woman in the 1935 group, who ate 18 oz dates during the week, has been excluded from the average

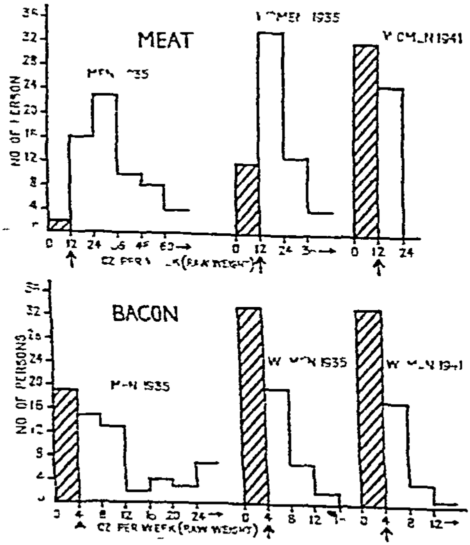

FIG 3—Frequency distribution of meat and bacon intakes.

Only one woman ate any tomato in the 1941 survey, and she had a very small amount In 1935 the intakes averaged nearly 5 oz a week, and ranged from none to 38 oz Neither survey covered the season when raw salads were abundant, and the intakes were equally low in 1935 and 1941

Meat—The average consumption of unrationed meat fell as indeed would be expected On both occasions it consisted chiefly of sausages and meat bought ready cooked Allowance has been made for the smaller amount of meat in war-time sausages

Fish—In 1941 the average intake of fresh and dried fish was less than half what it had been in 1935 Increased price was probably the chief reason for this Supplies were undoubtedly less, but the greater cost led to a decreased demand Hence there was not much apparent shortage Of the women in 1941, 30 partook of some form of tinned fish, the supplies of which were still ample at that time In 1935, when other foods were cheap and easy to obtain, only 12 of the women seem to have been attracted by this kind of fish and the per-caput consumption was only ¼ as great

Eggs—Both the 1935 and 1941 surveys covered the season of the year when eggs were relatively plentiful Although the number of eggs eaten was less in the 1941 survey, there is no doubt that the difference would have been much greater had the survey been made at another season of the year Before the war there were plentiful supplies of imported eggs during the winter months

TABLE III—AVERAGE INTAKES OF RESTRICTED FOODS IN 1935 AND 1941 (OZ. PER WEEK)

		Women 1935	Women 1941
Fruit	raw	29·1	0·6
	cooked (excluding sugar)	7·5	11·4
	tinned	1·7	1·5
	dried	1·1	0·8
Tomato, raw and cooked		4·9	0
Raw salad (excluding tomato)		2·5	2·5
Unrationed meat (raw weight)		7·4	4·7
Fish	fresh and dried (raw weight)	9·3	4·0
	tinned	0·4	1·1
Eggs (number)		4·2	3·2
Cream		1·7	0
Cake		11·5	11·7
Biscuits		3·2	5·0
Sweets and chocolates		3·9	1·9
Milk (pints)		3·3	4·6

Cream—In the 1935 survey more than two-thirds of the women had some cream during the week of investigation, and the average consumption was 1·7 oz a week In 1941 the sale of fresh cream was prohibited , 3 of the women entered small amounts of cream on their records, but in each case it came out of a tin

Confectionery—The figures for cakes and biscuits justify rather more comment In spite of the apparent scarcity of cake and biscuits in the shops, the average consumption of cake was the same in 1941 as it had been in 1935 and the intake of biscuits had increased. The proportion of the cake which was home-made was likely to have been higher in 1935, when there were no restrictions on fat sugar and eggs Now the housewife cannot make cake as she formerly did, and she tries to buy it ready made Hence, the apparent scarcity is probably partly due to an increased demand The same applies to biscuits People who never bought biscuits before are undoubtedly buying them now As shopping becomes more difficult the housewife is only too glad to be able to get biscuits to make up for the fruit and sweets that she cannot now obtain These results are consistent with the fact that there has been an appreciable increase in the manufacture of cakes and biscuits since the prewar period, in spite of reduced allocations of fat and sugar The only biscuits now being made are the plainer varieties

The amount of sweets and chocolates eaten was about half as much in the 1941 survey as it had been in 1935 ; 14 of the 1935 group and 20 of those taking part in the

1941 survey ate no sweets or chocolates during the experimental week

Milk has been included among the restricted foods, although the restrictions in supplies did not come into force until half way through the 1941 experiment The figures include the milk used for making puddings and other cooked dishes, as well as that taken in liquid form It will be seen that the average amount of milk consumed was nearly 50% higher in 1941 than in 1935 This higher consumption was not due to more milk puddings being eaten, but to larger quantities of milk being drunk as such, or taken in tea or other beverages The " drink more milk " campaign, which was carried out between the time of the first survey and the outbreak of war, evidently caused such an increase in the demand for milk that even after retail distribution had been cut by ¼ consumption was still 50% above what it had been six years previously

TABLE IV—AVERAGE INTAKES OF PLENTIFUL FOODS IN 1935 AND 1941 (OZ PER WEEK)

	Women 1935	Women 1941
Bread	35 2	45 6
Flour in puddings and savoury dishes	3 9	5 1
Oatmeal	0 5	1 6
Rice	0 5	1
Proprietary cereals	0 8	1 4
Other cereals (cornflour, &c)	0 4	0 7
Potatoes, cooked	21 1	33
Green vegetables, cooked	9 2	13 9
Root vegetables, cooked	4 7	7 4
Legumes, cooked	2 8	2 4

PLENTIFUL FOODS

It is clear from the results already discussed that people were eating smaller amounts of a great many foods in March, 1941, than they had been before the war The general principle of rationing already enumerated states that there should have been a corresponding increase in the consumption of others Table IV shows that this was indeed the case, for in the 1941 survey the women were eating more bread, more flour, more rice and much more oatmeal than their opposite numbers in 1935 These changes in rice and oatmeal were brought about in two ways More people ate them, and those who did eat them ate more of them Thus, in 1935, 14 women ate porridge, and had on average 2 2 oz oatmeal each In 1941, 27 women recorded porridge, and ate 3 5 oz per head Rice was chiefly eaten in rice pudding In 1935, 30 mentioned this cereal In 1941, the number had risen to 45

" Proprietary cereals " include bread substitutes such as Ryvita, as well as breakfast cereals In spite of an apparent shortage, the average intake of these foods increased Several reasons may be suggested for this During the years 1935–39 proprietary breakfast cereals may have become more popular Although more was being eaten in 1941 than in 1935, it may well have been less than the amount eaten in 1939 Further, the scarcity of materials for breakfast dishes such as eggs, tomatoes and fruit had led to an increased demand for porridge and other cereal foods , 26 of the women ate one or other of the proprietary cereals during their week of weighing in 1941 as against 15 in 1935

" Other cereals " consists chiefly of custard powder, and this figure also showed an increase

Turning now to the vegetables, potatoes were being eaten in somewhat larger amounts in the 1941 survey In 1935 the average consumption was 3 oz a day In spring 1941 it had risen to 4 7 oz It is evident, however, that women of this social class have not yet become potato-conscious Potatoes provide more calories to the acre than any other food, and they can readily be grown in this country When imports are restricted, as they are at the present time, this vegetable ought to provide us with more than 6% of our calories One person in the 1941 survey ate 300 oz during the week, or 43 oz a day ! She was excluded in calculating the average She ate them at three meals every day, and she obtained 49% of her calories in this form The consumption of cooked green and root vegetables had also increased All but 2 of the women on both occasions recorded some sort of green vegetable , 19 of the women in 1935 and 7 of those in 1941 ate no root vegetable of any kind Legumes consisted chiefly of dried haricot and butter beans, baked beans and tinned peas There was no significant change in consumption

CALORIES

The average daily calorie intake in 1935 was 2187, with a standard deviation of 388 In 1941 the mean was 2137, with a standard deviation of 420 These average figures are not significantly different from one another Thus, the principle held Deprived of the calories which they had been accustomed to getting from their rationed foods, appetite and instinct had driven these women to make good the loss by increasing their consumption of unrationed and plentiful foods

This 1941 dietary survey was limited to women The 1935 surveys demonstrated clearly that before any restrictions were imposed men were eating more of nearly every type of foodstuff In the present system of rationing men get the same allowances as women In order to maintain their calories, therefore, they require to increase their intakes of the unrationed foods more than women Thus, at the time of the 1941 survey the rationed foods provided about 600 calories a day The men taking part in the 1935 survey were obtaining about 1400 calories a day from the foods that are now rationed The women derived 850 calories a day from this source Hence, the men would have had to find 800 calories a day from unrationed sources, and the women 250 calories. In terms of food, the men would have to eat another 11 oz bread or 32 oz potato a day to make good this deficit The women required 3½ oz bread or 10 oz potato Actually, the women's potato and bread intakes had risen by less than these amounts, for they had also increased their consumption of oatmeal and other foods of this kind

CHEMICAL COMPOSITION OF THE DIETS

Table V shows the calorific values and chemical composition of the diets in 1935 and 1941 McCance and Widdowson's (1940) tables of the composition of foods were used for the calculations It will be seen that, although the total calories were much the same, their distribution between fat and carbohydrate had altered considerably Relatively more carbohydrate and less fat were being eaten in spring 1941 The differences in both cases are statistically significant The amount of total protein, as always, remained remarkably constant The figure for animal protein, however, showed a significant reduction because of the smaller amounts of meat, fish and cheese which were available in 1941 In the 1941 survey only 4 people recorded any alcoholic drink and the amounts were too small to affect the average calories of the group

TABLE V—CHEMICAL COMPOSITION OF THE DAILY DIETS

	1935		1941	
	Average	Standard deviation	Average	Standard deviation
Calories	2187	388	2137	420
Total protein (g)	67 3	12 4	64	12
Animal protein (g)	46	11 3	33 8	8 4
Fat (g)	100 5	20 6	78 4	16
Carbohydrate (g)	233	58 5	280	67
Calories from protein (per cent)	12 8		12 2	
Calories from fat (per cent)	42 7		34 1	
Calories from carbohydrate (per cent)	43 6		53 7	
Calcium (g)	0 63	0 16	0 77	0 25
Phosphorus (g)	1 13	0 25	1 14	0 29
Total iron (mg)	11 4	2 50	12 2	2 68
Inorganic iron (mg)	7 9	1 64	9 2	2 34

The calcium intake was significantly higher in 1941 than it was in 1935 The increased intake of milk almost exactly accounts for this, and the decrease in the consumption of cheese has been made good by an increased consumption of green vegetables The amounts of phosphorus in the diets were almost identical in the two surveys Both total and inorganic iron were higher in the war-time dietaries The iron acquired from the increased bread and vegetables more than made up for the iron sacrificed by the shortage of meat

VITAMIN C

The question has often arisen as to whether the war-time dietary is deficient in vitamin C To obtain some information on this point the vitamin C intakes of the individual women have been calculated as accurately as possible from the 1935 and 1941 records The most reliable figures which are available for the vitamin C in raw and cooked fruit and vegetables were kindly supplied by Miss M Olliver A sliding scale was adopted for potatoes, since it has been shown that the vitamin C in this vegetable varies greatly from one time of year to another Table VI shows the results The amount of the vitamin C derived from various sources on the two occasions is also shown It will be seen at once that the average intake in 1941 was only half what it had been in 1935

In 1935 fruit supplied ten times as much vitamin C as it did in 1941 and the women in the first survey got more from this source alone than those in the second obtained from the whole of their diet The amounts provided by vegetables and milk were a little higher in 1941, due to an increased consumption of these foods Jam provided the same amount on the two occasions in spite of the increased consumption of this food This was because the vitamin C in jam varies widely according to the fruit from which it is made In 1935 more black-currant jam, rich in C, was eaten

TABLE VI—AVERAGE VITAMIN C INTAKES (MG PER DAY)

Source	Women 1935	Women 1941
Fruit	37 5	2 8
Vegetables	15 6	19 4
Jam and marmalade	1 5	1 5
Milk	2 4	3 2
Total from all sources	57	26 9
Maximum	140	85 2
Minimum	10 2	7 7
Standard deviation	31	9 4

Fig 4 shows the frequency distribution of the vitamin C intakes It will be seen that in 1935 9 women were having less than 25 mg a day, 39 between 25 and 75 mg, and 15 more than 75 mg In 1941 26 out of 57 women had less than 25 mg, and only one had more than 75 mg, this was the woman who ate 300 oz of potato during the week, and she derived 43 mg of ascorbic acid a day from this source alone

The Technical Commission (1938) suggested that the vitamin C requirement of adults was covered by 30 mg of ascorbic acid daily The present results suggest that this is true, but that very much smaller amounts will suffice, for in the 1941 survey 41 women were having less than 30 mg a day, and had probably been having so for 3–6 months There were moreover, no manifest signs of scurvy among them nor indeed have there been any reports of scurvy even among sections of the community less privileged than the women here investigated Fox (1940) also came to the conclusion that the vitamin C requirement was much less than others (Harris 1939, Bacharach 1940) have supposed

The vitamin C intake in war-time must be expected to vary from one season to another as it has ceased to do in peace-time This survey was carried out in the lean season There was no fresh fruit, or raw vegetable salads, and even potatoes were at their lowest ebb No doubt the intakes would have been much higher in the summer and autumn

SUMMARY

The records of a dietary survey carried out in 1935 on 63 men and 63 women of the English middle class have been re-analysed At that time the men were eating an average of twice as much sugar and bacon, three times as much meat butter and jam, and five times as much cheese, as the rations allowed them in spring 1941 The women were eating less of these foods, but the quantities of all of them except sugar exceeded their rations in spring 1941

An individual dietary survey was carried out in spring 1941 on 57 women of a similar social class They were found to be eating much less raw fruit and less unrationed meat fish and sweets and chocolates than the women surveyed in 1935 Milk, bread and other cereal foods, potatoes and other vegetables were being consumed in larger amounts in the 1941 survey

The women in the 1941 survey had maintained their calories at their prewar level by substituting unrationed carbohydrate for rationed fat Their protein and phosphorus intakes were unchanged their calcium and iron intakes were higher than they had been in 1935 The amount of animal protein was less in the war-time dietary.

The average vitamin-C intake in 1935 was 57 mg a day and 27 mg in 1941 This decrease was due entirely to the disappearance of raw fruit from the market Three-quarters of the women in the 1941 survey were having less than 30 mg a day

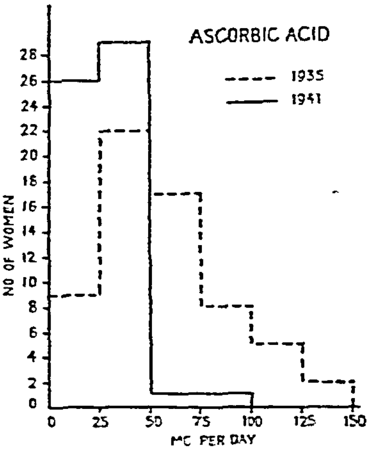

FIG 4—Frequency distribution of vitamin-C intakes

We are grateful to all those who have participated in this investigation by weighing their food We wish to thank Dr R A McCance for his advice and assistance in the preparation of the results for publication We are indebted to the Medical Research Council for grants and expenses

SNEEZING AND THE SPREAD OF INFECTION

R B BOURDILLON, D M OXFD
O M LIDWELL, PH.D OXFD

(From the National Institute for Medical Research)

RECENT developments in flash photography[1] have increased our knowledge of the particles projected in human sneezing to a point which justifies some practical conclusions as to the best methods of preventing infection from sneezes American workers[2] have shown that in an ordinary sneeze many thousands of droplets are projected at an initial velocity which may occasionally be as high as 150 ft per sec and that most of these droplets come from the mouth Our own studies have given similar results in many instances, and have shown further points as follows

Sources of spray—While in most photographs the

---

[1] Edgerton H E, Germeshausen, K J and Grier H E *J appl Physics* 1937 8, 2

[2] Jennison, M W *Sci Mon N Y* 1941, 52, 24

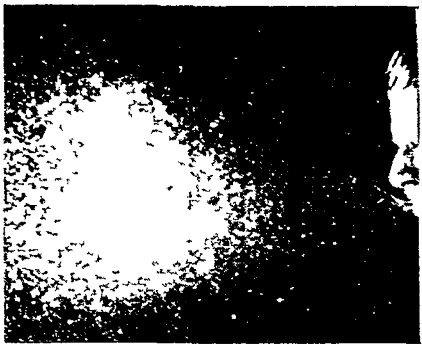

FIG 1—Discharge chiefly from mouth

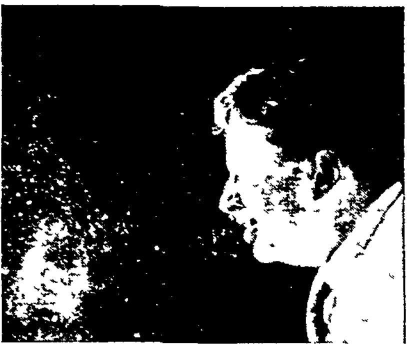

FIG 2—Discharge from both mouth and nose

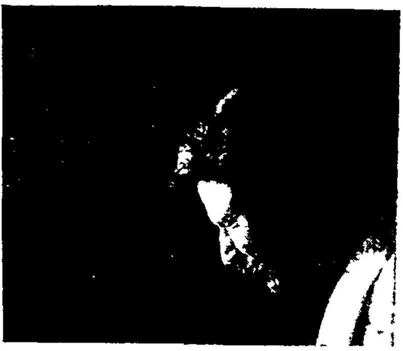

FIG 3—Discharge from nose only

majority of the droplets come from the mouth as in fig 1, in some cases a purely nasal discharge is seen as in fig 3, and in others a mixed oral and nasal discharge is seen as in fig 2 In this photograph it is evident that the nasal discharge is being blown forward by the air stream from the mouth, and so goes forwards rather than downwards *It is evidently not justifiable to conclude, as has been* suggested that nasal discharges are unimportant in ordinary sneezes

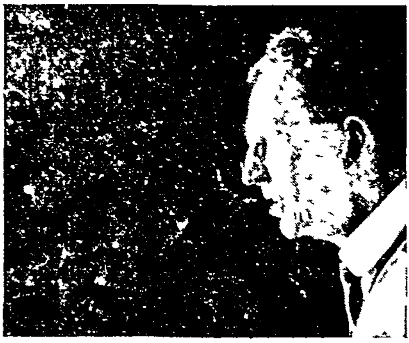

FIG 4—Teeth open, pressure low Large drops with few small ones

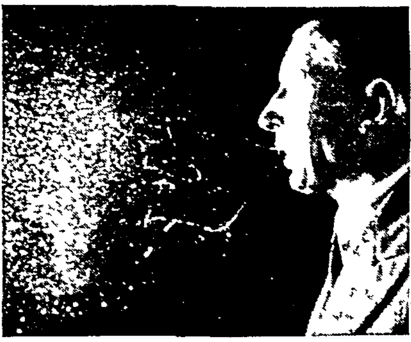

FIG 5—Strings of mucus are common

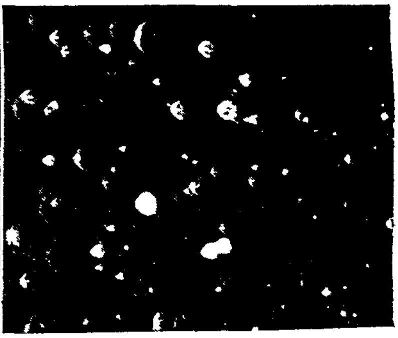

FIG 6—Part of fig 2 enlarged to two-thirds life size

Size of droplets varies greatly in different sneezes. Tightly closed teeth or lips and high expiratory pressure give a fine spray as in fig 1 Open jaws and lips and moderated expiration give relatively few large drops as in fig 4. Thus a sneeze with open mouth is probably less dangerous to other people, owing to the rapid fall to the ground of large drops, as well as being safer for the subject, owing to the reduced pressure in nose and throat Strings of mucus are common, as seen in fig 5 Fig 6* shows the remarkable appearance of the droplets when photographed while in motion The pointed outline of the faster moving droplets is possibly an artefact

Distance projected —In a vigorous sneeze very large numbers of droplets will hit a vertical plate 3 ft distant from, and a few inches lower than the subject's mouth A small number of large droplets reach a plate 5 ft distant and 1–1½ ft. below the subject's mouth The range of danger from direct projectile infection is not less than 4 ft but will rarely exceed 6 ft for a person at the same height as the sneeze.

Infectivity of spray —Fig 7 shows a culture plate of 9 in diameter which was placed vertically in the path of the sneeze shown in fig 1, at a distance of 3 ft from the subject's nose The subject was in good health and free from cold (in August), but the serum-agar plate after 14 hours incubation showed over 19,000 colonies These colonies came from at least 19,000 separate droplets, and no attempt was made to estimate the number of bacteria per droplet While in this case the bacteria are mostly harmless ones *from the front of the mouth*, it is clear that very many of the droplets in a sneeze do contain living bacteria It seems reasonable to infer that in acute infections of the upper respiratory tract droplets from sneezes are highly infective

Presence of droplet nuclei —Tests have been made with a subject sneezing in a small closed room of 800 cu ft. capacity, with floor and table oiled as a precaution against dust Culture plates of 9 in diameter were exposed on a table 5 ft. from a subject who sneezed twice On one plate uncovered only for the 20 min period from 10 to 30 min after the sneezes no less than 493 colonies grew A similar plate exposed for 15 min in a control test without the sneezes showed only 5 colonies A series of tests of this type have shown conclusively that a large number of the bacteria-carrying particles from a sneeze are small enough to remain suspended for

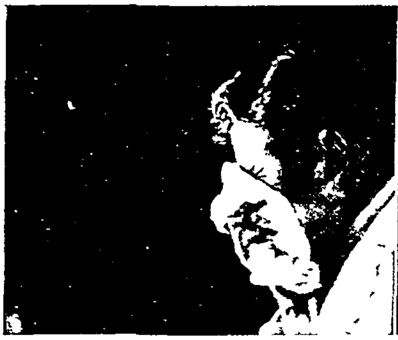

FIG 8—A sneeze well covered with an ordinary handkerchief

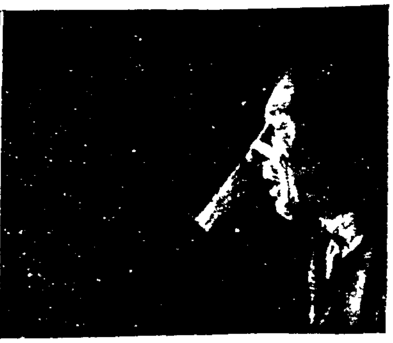

FIG 10—A sneeze into a cheap mask Note three droplets only escaping downwards

---

* The enlargement is such that the subject's head if included would be two thirds life size, but the true size of the droplets may be less than their apparent size if they are appreciably out of the focal plane

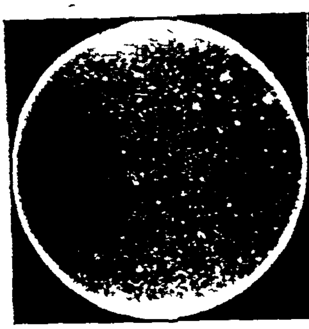

FIG 7—19 000 colonies of bacteria on a culture plate exposed to the sneeze shown in fig 1

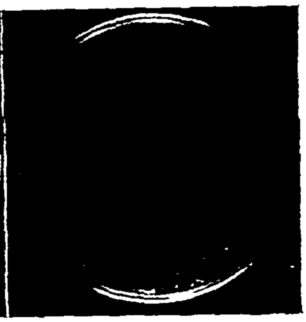

FIG 9—One colony only on a culture plate exposed to a sneeze as in fig 8

over 15 min before falling on the culture plates Such particles come within the category defined by Wells[3] as "droplet nuclei," and are certainly capable of conveying infection under suitable conditions

HYGIENIC MEASURES

To prevent the spread of infection when sneezing indoors one or more of the following measures is usually adopted We have placed them in order of estimated efficiency

Sneezing directly into a coal or gas fire (from a short distance) does in our opinion, ensure sterilisation of nearly all the droplets since owing to the chimney draught few droplets will escape being carried into the fire or up the chimney

The careful use of a large handkerchief—Figs 8 and 9 show that this method can be very efficient In fig 8 the subject is sneezing vigorously at the moment of exposure, but no droplets can be seen escaping Fig 9 shows a culture plate similar to that shown in fig 7 but exposed in front of a sneeze trapped by a handkerchief as shown in fig 8 This plate contained one colony only

A transparent mask—Fig 10 shows a vigorous sneeze covered by a cheap mask of cellulose acetate 5½ in × 5½ in, such as has been provided in reserve for London shelter populations The droplets from the sneeze can be seen collected inside the mask except for three which are seen below the mask in line with its surface The high apparent efficiency of this type of mask is rather surprising, and it is possible that some very fine droplets are escaping sideways without being visible in the photograph

A gauze mask of good quality can be fairly efficient for a single sneeze, but becomes messy and unpleasant after multiple sneezes, since unlike a transparent plastic, gauze cannot be wiped clean and dry

The hand—Figs. 11 and 12 show how very inefficient the hand is as a sneeze guard With the closed hand in fig 11 inefficiency would be expected but with the open hand placed in position well before the sneeze occurred, as in fig 12, more protection might be expected. Its failure is due to the upward deflection of the air stream which can be seen in this photograph and has been confirmed in another instance

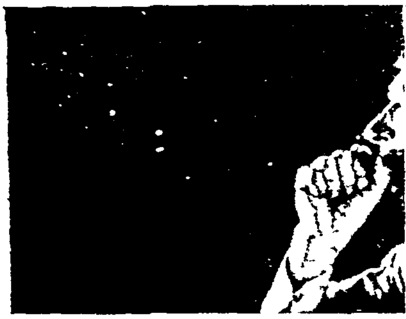

FIG 11—The closed hand is very inefficient

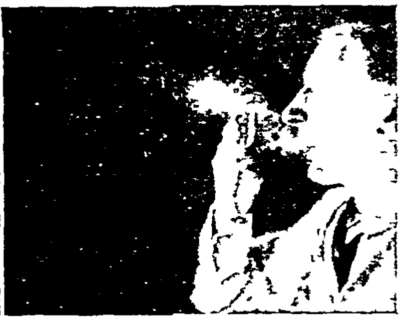

FIG 12—The open hand may only stop a fraction of the particles and deflect the rest upwards

TECHNIQUE

Few people can sneeze regularly in front of a camera, owing to the ease with which the sneezing reflex is inhibited We found a number of subjects who could do it occasionally after taking snuff, and two who could sneeze regularly, one after taking snuff, and one after inhaling minute quantities of ω-bromaceto 6 methoxy quinoline hydrobromide

A stroboscope lamp was used with mercury kathode and a special igniting electrode, supplied by British Thomson-Houston Ltd The flash was made by discharging through this a battery of 100 × 1 μf dry condensers charged to 2100 volts from a series of dry batteries and accumulators A cylindrical parabolic reflector of duralumin was placed behind the lamp with small electric heaters at the sides to keep the lamp gently warmed The flash was timed with a hand-controlled switch by an observer who watched the onset of each sneeze The camera C, lamp L, and subject S were placed at the corners of a triangle of dimensions approximately as follows LC 55 in, LS 36 in, CS 41 in The subject sneezed on a line passing close to the lamp, but between it and the camera The lamp reflector was just to the left of the portions of the photographs reproduced here This system gives maximum illumination as the droplets approach the lamp—i e, at the farthest distance included in the photograph It is in contrast to the system used by most American workers, who place the lamp very close to the subject's head Owing to the very brief duration of the flash the subject is not dazzled, even if his eyes are open

SUMMARY

The droplets from a sneeze contain many fine bacteria-laden particles which remain suspended in the air for more than ten minutes A large handkerchief carefully used prevents the scattering of these droplets, and a simple impermeable mask collects the vast majority of them The use of the hand for checking such scattering is very inefficient

We wish to thank the research staff of British Thomson-Houston Ltd for advice on the use of this lamp, and the various subjects who have patiently sneezed for this study We are also indebted to Mr S F Wilkinson for suggesting the taking of some of these photographs

CORROSIVE STRICTURE OF THE STOMACH

WITHOUT INVOLVEMENT OF THE ŒSOPHAGUS

C A R SCHULENBURG M B Cape Town, F R C S
LATELY SURGEON IN AN E M S HOSPITAL

CICATRICIAL stricture of the œsophagus following ingestion of corrosive acids or alkalis is well known, and lesions of the stomach in association with an œsophageal stricture have been reported (Sager and Jenkins 1935, Vinson and Hartmann 1928) but stricture of the stomach with an unharmed œsophagus seems to be very rare, at any rate in England though the condition is fully dealt with in a number of foreign papers

The only recorded case in the English language is described by Vinson and Harrington (1929) A man of 59 accidentally swallowed formaldehyde, subsequently developing signs of obstruction in the stomach, barium meal 4 weeks after the episode showed a double stricture of the stomach which was confirmed at operation, there had been no permanent damage to the œsophagus There is also a case in the autopsy records at Guy's Hospital (Bishop P M F, personal communication) of a woman of 61 who swallowed hydrochloric acid and developed signs of pyloric obstruction, she died 4 weeks after admission from bronchopneumonia At autopsy the œsophagus was found to be free from any lesion, while the stomach showed a tight, fibrous, annular stricture for 3 cm above the pylorus. Prof Grey Turner, who has had extensive experience of strictures of the œsophagus and other lesions following the ingestion of corrosives, tells me that he knows of only one case where pyloric stenosis

---

[3] Wells, W F *Amer J Hyg* 1934 20 611

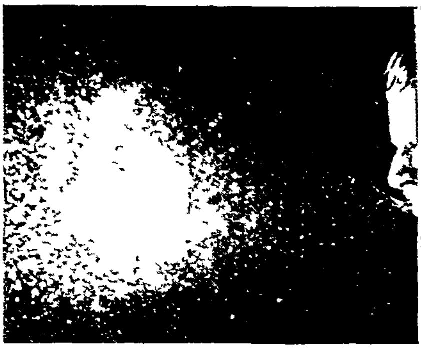

FIG 1—Discharge chiefly from mouth

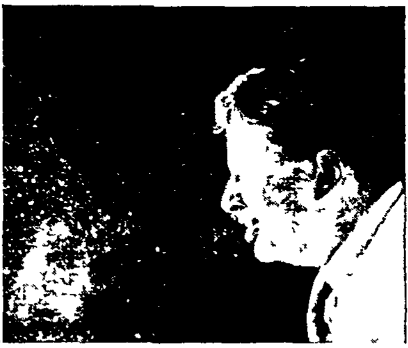

FIG 2—Discharge from both mouth and nose

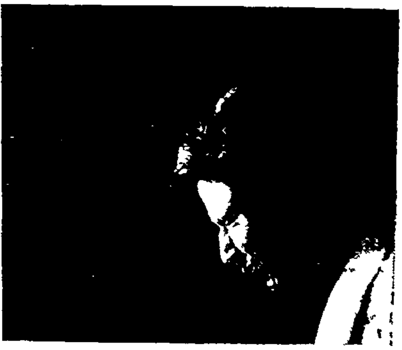

FIG 3—Discharge from nose only

majority of the droplets come from the mouth as in fig 1, in some cases a purely nasal discharge is seen as in fig 3, and in others a mixed oral and nasal discharge is seen as in fig 2 In this photograph it is evident that the nasal discharge is being blown forward by the air stream from the mouth, and so goes forwards rather than downwards It is evidently not justifiable to conclude, as has been suggested, that nasal discharges are unimportant in ordinary sneezes

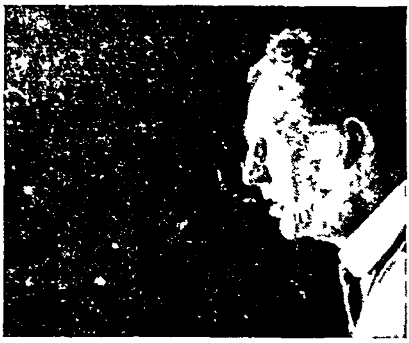

FIG 4—Teeth open, pressure low Large drops with few small ones

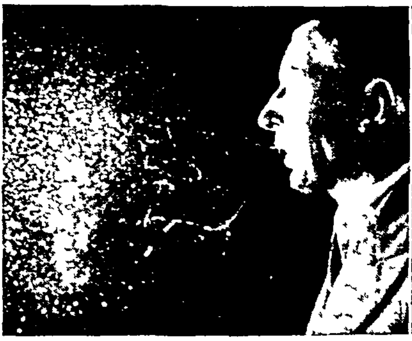

FIG. 5—Strings of mucus are common

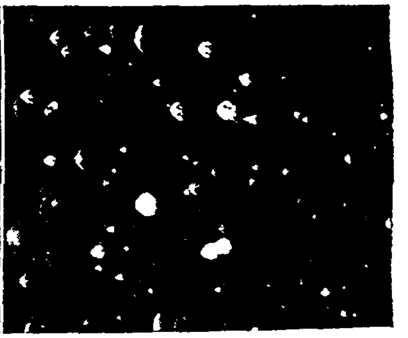

FIG 6—Part of fig 2 enlarged to two thirds life size.

Size of droplets varies greatly in different sneezes. Tightly closed teeth or lips and high expiratory pressure give a fine spray as in fig 1 Open jaws and lips and moderated expiration give relatively few large drops as in fig. 4. Thus a sneeze with open mouth is probably less dangerous to other people, owing to the rapid fall to the ground of large drops, as well as being safer for the subject, owing to the reduced pressure in nose and throat Strings of mucus are common, as seen in fig 5 Fig 6* shows the remarkable appearance of the droplets when photographed while in motion The pointed outline of the faster moving droplets is possibly an artefact

Distance projected—In a vigorous sneeze very large numbers of droplets will hit a vertical plate 3 ft distant from, and a few inches lower than, the subject's mouth A small number of large droplets reach a plate 5 ft distant and 1–1½ ft. below the subject's mouth The range of danger from direct-projectile infection is not less than 4 ft but will rarely exceed 6 ft for a person at the same height as the sneeze

Infectivity of spray—Fig 7 shows a culture plate of 9 in diameter which was placed vertically in the path of the sneeze shown in fig 1, at a distance of 3 ft from the subject's nose The subject was in good health and free from cold (in August), but the serum-agar plate after 14 hours incubation showed over 19,000 colonies These colonies came from at least 19,000 separate droplets, and no attempt was made to estimate the number of bacteria per droplet While in this case the bacteria are mostly harmless ones from the front of the mouth, it is clear that very many of the droplets in a sneeze do contain living bacteria It seems reasonable to infer that in acute infections of the upper respiratory tract droplets from sneezes are highly infective

CORROSIVE STRICTURE OF THE STOMACH

WITHOUT INVOLVEMENT OF THE ŒSOPHAGUS

C A R SCHULENBURG, M B Cape Town, F R C S
LATELY SURGEON IN AN E M S HOSPITAL

CICATRICIAL stricture of the œsophagus following ingestion of corrosive acids or alkalis is well known, and lesions of the stomach in association with an œsophageal stricture have been reported (Sager and Jenkins 1935, Vinson and Hartmann 1928), but stricture of the stomach with an unharmed œsophagus seems to be very rare, at any rate in England, though the condition is fully dealt with in a number of foreign papers

The only recorded case in the English language is described by Vinson and Harrington (1929) A man of 59 accidentally swallowed formaldehyde, subsequently developing signs of obstruction in the stomach, barium meal 4 weeks after the episode showed a double stricture of the stomach, which was confirmed at operation, there had been no permanent damage to the œsophagus There is also a case in the autopsy records at Guy's Hospital (Bishop P M F, personal communication) of a woman of 61 who swallowed hydrochloric acid and developed signs of pyloric obstruction, she died 4 weeks after admission from bronchopneumonia At autopsy the œsophagus was found to be free from any lesion, while the stomach showed a tight, fibrous, annular stricture for 3 cm above the pylorus. Prof. Grey Turner, who has had extensive experience of strictures of the œsophagus and other lesions following the ingestion of corrosives, tells me that he knows of only one case where pyloric stenosis

---

3 Wells W F *Amer J Hyg* 1934, 20, 611

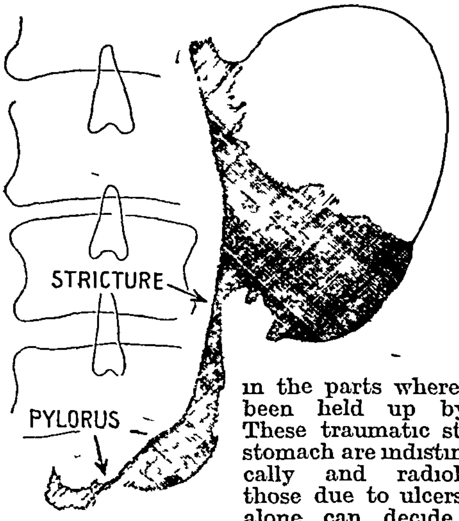
occurred after the swallowing of lysol Similar cases have been reported by Pop and Galdau (1928a and b), Bock and Hin (1931), Popp (1931) and Faynberg (1935) Orator (1929) reviews the clinical findings on the basis of 34 collected cases, and Petrov (1935) reports 41 operations for burns of the stomach by strong acids and alkalis Their conclusions are similar

1 Acid burns are much more liable to cause gastric stenosis than alkalis, which affect mainly the œsophagus

2 The site of stricture formation is almost invariably the pyloric and prepyloric regions

3 The surgical procedures for relief are determined by the stage at which the patient is seen In the earliest stages, with gross damage to the stomach, jejunostomy is the operation of choice At a later stage, when stenosis with obstruction is established, gastrojejunostomy is the only rational procedure

An interesting experimental study is provided by Testa (1938) A small amount of caustic soda, with added barium, was introduced into the œsophagus of dogs, and its passage observed by X rays In the stomach, the alkali flowed along the lesser curvature and a severe pre-antral spasm was produced which lasted for a variable time and was followed by peristalsis and relaxation of the spasm and of the pylorus Subsequent examination showed the severest trauma and changes to be in the parts where the fluid had been held up by the spasm These traumatic strictures of the stomach are indistinguishable clinically and radiologically from those due to ulcers The history alone can decide the question The prepyloric strictures often simulate carcinoma, but the defect in the radiogram has a smoother outline than in cancer



Tracing of radiogram after barium meal

CASE-HISTORY

A railway station attendant of 52 was admitted to St Alfege's Hospital on Nov 26, 1940, with a history of having swallowed 1 oz of concentrated hydrochloric acid about two hours before Until this time he had always been well He had vomited twice before admission, and had some epigastric pain His voice was thick and slurred, and his tongue, cheeks and fauces were badly burned Routine immediate treatment was applied Four days after admission he complained of difficulty in swallowing and epigastric discomfort A barium swallow was given 16 days after admission, but showed no œsophageal delay or stricture On Dec 19 (23 days after admission) a barium meal X ray examination was made by Dr K J Yeo, and a stricture of the stomach proximal to the pylorus was demonstrated, the distal pocket being collapsed and empty (see figure) On Dec 30 (34 days after admission) the patient began to vomit daily He was then transferred to the Southern Hospital, Dartford, where the vomiting was controlled for some time by small, frequent feeds Improvement was not sustained, however, and when I saw him first, on Jan 29, he presented a classical picture of pyloric obstruction, with dilated stomach, succussion splash and visible peristalsis The stomach was aspirated continuously through an indwelling Ryle's tube, and continuous intravenous saline with glucose was administered

Operation was performed on Jan 30 under local analgesia The stomach was exposed through a high midline incision, it showed a tight, fibrous stricture about 2 in proximal to the pylorus, the greater curvature being drawn up to the lesser curvature by the scarring The proximal pouch of the stomach was much hypertrophied and dilated, while the distal pocket was collapsed and empty There was no evidence of malignant disease, and there were no enlarged glands along the curvatures The gall-bladder was small and contained one stone An anterior, antecolic gastrojejunostomy was performed, and the abdominal wall was sutured with interrupted buried floss silk sutures Intravenous fluids and aspiration of the stomach were continued for a further 36 hours, and the patient made a good recovery A barium meal on March 13 showed the œsophagus normal and the stoma functioning well The distal part of the stomach was faintly outlined and showed the stricture, which allowed the passage of only a small amount of barium Œsophagoscopy on April 16 showed no signs of stricture or ulceration, and the cardia was normal By May the patient had gained a stone and a half in weight, was eating well, and had no abdominal discomfort

COMMENT

A constant feature of the recorded cases is the rapidity of onset of the stenosis One of the cases reported by Pop and Galdau had a complete stricture 19 days after swallowing caustic soda, while the cases mentioned in this paper had developed tight strictures within 4 weeks This can be explained by rapid healing with fibrosis, following intense localised destruction of mucous membrane and stomach coats by the corrosive while held up by the pyloric and pre-antral spasm This holding up of the corrosive by spasm was well demonstrated in Testa's experiments The intensity of this destruction is shown by the fact that acute perforation of the stomach wall can occur if the acid remains localised to one area The radiographic appearances may be indistinguishable from those produced by carcinoma or sclerosing ulcers This is important, because malignant disease must be excluded or appropriately treated at operation The preponderance of stomach lesions where acid has been swallowed and of œsophageal stenosis where alkali has been taken is noted by all observers, but no rational explanation has been given Complete absence of injury to the œsophagus was demonstrated in the case recorded here by X-ray examination and œsophagoscopy.

I wish to thank Dr W Allen Daley, medical officer of health to the London County Council, for permission to publish this case, and Dr P M F Bishop for a note of the case at Guy's Hospital

Medical Societies

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

THE annual congress of this society took place at Trinity College, Cambridge, on Sept 4 and 5 under the presidency of Mr R AFFLECK GREEVES (London) who read a paper on *œdema of the macula* He thought this condition was always accompanied by deterioration of central vision, varying in degree according to the severity of the œdema The distortion of straight lines was a common symptom and a valuable diagnostic point A sense of diminution in the size of objects was also common The clinical signs were loss of retinal transparency, though in the slightest degrees of œdema a minute ophthalmoscopic examination and a careful comparison with the appearance of the macula of the other eye might be necessary for its detection After œdema central vision might be restored, improve up to a point, remain permanently reduced (possibly with some visual distortion), or be permanently destroyed, as in most cases of central venous thrombosis The ophthalmoscopic appearance of the macula might return to normal, but some permanent pigmentary disturbance could often be seen A complete restoration of the normal appearance of the fundus did not always connote full recovery of vision and a fine granular disturbance might persist at the macula even when normal vision was restored Mr Greeves later described a case of *choroidal sarcoma at the macula* He had encountered 10 such cases, which varied greatly in malignancy

Mr HUMPHREY NEAME (London) described 17 cases of *dendritic ulcer of the cornea*, 8 of which were associated with herpes simplex He had treated the ulcers mainly by hot bathing, with atropine pad and bandage, and rest He thought that dendritic ulcers should be given a chance to heal without carbolisation

In his paper on *unusual symptoms of migraine* Mr T HARRISON BUTLER (Birmingham) said that in a few cases the headache was due to ocular defect But a headache of recent origin must be due to some recent cause, and an ocular defect which had been present for some years or from birth was unlikely suddenly and independently to give rise to headache Large errors of refraction and muscle balance did not generally cause headache, and if headache was present it was often not relieved by glasses In the discussion which followed the PRESIDENT was of opinion that headaches were often wrongly attributed to errors of refraction, fatigue was an outstanding cause of migraine Mr FRANK HECKFORD (Ryde) drew attention to the large numbers of young people between 15 and 25 among whom disturbances of this kind were common, due to some vasomotor irregularity They nearly always complained of cold hands and feet and of a feeling of weight on the top of the head, accentuated in girls during their periods

Sir JOHN PARSONS, F R S (London) embodied a memorandum sent to the Army Council by a subcommittee of the Military Personnel Research Committee in his paper on *eye protection in warfare* The committee did not favour a metal vizor of the Cruise type, but Sir RICHARD CRUISE (London) in the discussion said that it was the experience of ophthalmic surgeons that at least half of the war casualties with which they had to deal might be prevented by the provision of an eye protector The argument that the vizor under unusual conditions impeded visibility did not seem to him to hold good, for it need not be lowered when it was likely to handicap the wearer Mr HARRISON BUTLER pleaded that some such protection ought to be available for civilians who had to deal with incendiary bombs, and it was remitted to the council of the society to consider approaching the Ministry of Home Security with the suggestion that civilians to whom steel helmets had been issued should have the opportunity of buying for themselves some form of eye protection

The set discussion of the meeting on *ocular injuries resulting from the war* was opened by Dr O M DUTHIE (Manchester) He said that the number of eye casualties so far in the war was small He had seen only 50 severe injuries Ruptures were the most common of all war injuries Many especially those due to flying glass, were virtually untreatable, and even when they were not severe the end-results were deplorable Subconjunctival ruptures, with or without dislocation of the lens, were not infrequent Dr S ZUCKERMAN, who dealt with the problem of blast, held that although at high pressures, when casualties were close to the exploding bomb, there might be eye injuries due to blast, other injuries were likely in any case to prove fatal He pleaded for more statistics from those at work in eye hospitals and elsewhere, saying that until these were available they would be largely working in the dark on the question of protection

Of 100 patients Mr E B ALABASTER (Birmingham) had seen at a casualty hospital, 60 were cases of traumatic conjunctivitis, 21 were penetrating wounds, chiefly from metal or glass foreign bodies 6 were cases of corneal abrasion, 5 were cases of subconjunctival hæmorrhage, and 5 were injuries to the lids only There were single cases of central retinal block, detached retina and orbital cellulitis Of the 21 cases of penetrating wounds, 12 had required enucleation of one eye There was no case of complete bilateral loss of vision Mr HERBERT CAIGER (Sheffield) said that nothing had brought home to him the tragedy of this war so much as the case of a man aged 65 who was injured last November According to the man's story one eye was blown right out of the [illegible] other eye showed detachment of the retina More than twenty speakers took part in the discussion and several mentioned cases within their experience in which there had been no apparent injury to the eye by a blow or the penetration of a foreign body, and yet there was serious damage which could only be put down to blast Others claimed that no injury had been proved to have been produced solely by windage, that the term "blast" had become discredited, and that it would be better to call these lesions explosive injuries due to the impact of a foreign body on the eye One speaker told of a patient who had been thrown 40–50 ft, but had sustained only an injury to his knee, and complained that with one eye he could not see very well To this it was replied that one might with equal logic ascribe to blast the injuries received by falling from a high roof Mr A B NUTT (Sheffield) stressed the necessity for an ophthalmic surgeon to see eye cases as soon as possible after their admission to hospital, before they were lost in the surgical wards on account of other injuries Sometimes when there were extensive injuries to the face it was found that they had been stitched with thick silkworm gut without regard to alignment or the normal anatomy of the part Mr VICTOR PURVIS (London) said that on the night of Dec 29 last year, when there were widespread fires in London, 128 firemen were treated at Moorfields, of whom all but 4 had corneal or conjunctival foreign bodies None of them, however, needed inpatient treatment, and only 24 a second visit to hospital

Dr M D THAKORE (London) described a case of *pterygium* a rare condition in this country, though common in the Near East

Mr EUGENE WOLFF (London) gave an illustrated demonstration of *cholesterin spaces* in celloidin sections and of differential staining of the rods and cones Mr F A WILLIAMSON-NOBLE (London) read a paper on *unsealed retinal holes* It was open to question whether the presence of a hole with only a small peripheral loss of field and no interference with central vision required an operation, particularly in times like these when bombing raids might interfere with proper post-operative care

Squadron-Leader J H DOGGART described *refraction under war-time Service conditions* and suggested various expedients for speeding up refraction tests for Service men In the discussion which followed it was the general experience that malingering which was much in evidence during the last war, was almost unknown in this, but some men tried to prove that their eyesight was better than it was in order to obtain a particular job One speaker mentioned that it was not uncommon for the vision of recruits to be 6/9 on joining and shortly after entry into the army to be 6/6, but it was pointed out that the two examinations would probably be made by different people under different conditions

Mr FRANK LAW (London), who in the absence of the hon secretaries on service had arranged the meeting, read a paper on *squamous-celled carcinoma of the conjunctival surface of the lid* In this rare condition it was difficult to determine the site of origin of the neoplasm In the case he brought forward there was an ulcerated area, just nasal to the midline and some 6 mm across Removal was undertaken under general anæsthesia and repair effected by a simple plastic manœuvre Sutures were removed after six days and when last seen the patient complained of nothing either as regards comfort or appearance The specimen proved to be a squamous-celled carcinoma, but a point of even greater importance was the large amount of keratinisation and the many cell-nests found in a tumour arising in this situation

Mr G T W CASHELL (Reading) described a case of *orbital angioma* in a woman aged 43, and several members mentioned other cases occurring at a mature age although, according to the President such growths did not commonly increase in size save during the growing years Wing-Commander KEITH-LYLE had obtained remarkably successful results by operative treatment in cases of *diplopia due to head injury* arising from either paralysis or paresis of one or more of the extrinsic ocular muscles or a fracture of the orbit producing a displacement of the eyeball downwards Mr O GAYER MORGAN (London) described a case of *nystagmus synchronous with the pulse-rate* It was found to be labyrinthine in type, due to mastoid disease, operation for which stopped the nystagmus The last paper of this meeting was by Mr LINDSAY REA (London) on a remarkable case of keratitis, which he had successfully treated by the osmotic action of 10% warm magnesium sulphate applied for 5–10 min two or three times a day

Reviews of Books

The Extra Pharmacopœia (Martindale)

(22nd ed) In two volumes vol I London the Pharmaceutical Press Pp 1289 27*s* 6*d*

PUBLISHERS sometimes announce that a book is eagerly awaited and the wish may be father to the thought The first edition of the Extra Pharmacopœia in 1883 was sold out within a fortnight the twenty-second edition which appeared last Saturday is likely to meet the same fate For the book is a compendium of information otherwise only obtainable, in many instances, by reference to numerous textbooks and by arduous searching through the scientific literature And it happens that in the five years since the last edition appeared medicine has been enriched with synthetic remedies which have robbed many common ailments of their terror The new section headed sulphanilamidum with its 37 pages is the longest in the book Advance in knowledge of the sex hormones has doubled the section on œstradiol, and names like stilbœstrol and testosterone propionate occur for the first time And these are but two of the more striking examples of the new therapeutic agents described The book is also a complete guide to the law of poisons, the regulation of dangerous drugs, and the safeguarding of vaccines, sera, insulin and other therapeutic substances The Pharmaceutical Society of Great Britain deserves high praise for its enterprise in producing such a work under the circumstances of the times The only misprint occurs on p 1078 and the seriousness of the index is relieved by calling medical pigments just Pig

History of Magic and Experimental Science

Vols V and VI, the Sixteenth Century LYNN THORNDIKE London Humphrey Milford, Oxford University Press Pp 695 and 766 66*s* 6*d* each volume

Prof Thorndike's learned and detailed account of the study of magic and experimental science at a time when they were of almost equal importance in public estimation is a book for the scholar rather than the general reader He tells us that he has mentioned three thousand people by name, and has 1700 additional subjects in his index Among such profusion of trees, it is sometimes a little difficult to keep one's eye on the wood The thing which stands out with extreme clearness is the extraordinary surge and boiling up of Renaissance thought If we leave out of consideration altogether the greater names, such as Leonardo, Galileo and Copernicus, it is yet a most inspiring sight to watch the host of smaller men who launch themselves with headlong enthusiasm on the seas of controversy, ready to tackle any problem, from the structure of the universe, to the cure of demoniac possession by means of the liver of a black cat

The difficulties which beset any real experiment were almost insurmountable It was impossible to test or even to observe many of the natural—or unnatural—phenomena which were the accepted stock-in-trade of argument The discovery of the New World and of the printing press had between them laid bare a wealth of unimagined marvels, known of necessity by hearsay evidence only to most investigators Therefore though the reasoning might be close, nothing was too wildly improbable to serve as a premiss and it is indeed a wonder that through the storm and tumult, beneath the reciprocal shouts of "charlatan" and "empiric" we are able to discern the faint foreshadowing of psycho-analysis, the early—and very strange—gropings of biotherapy At the beginning of the century it was necessary to steer a wary course between the theories of Aristotle and ecclesiastical dogma, backed menacingly by the Holy Office With lapse of time both these influences rather waned, and from a quite early date it was possible to circumvent the Church by surprisingly simple devices, such as a postscript appended to one's pet and fully developed theory, stating that since it is contrary to the teaching of Scripture the author does not, of course believe it, or that all mention of God has been omitted in the discussion of dreams, because at this time he does not wish to mix profane and sacred matters The book of Genesis however was to remain a formidable stumbling-block to the scientist for two or three centuries longer

It is perhaps noteworthy that while science has developed so as to be almost unrecognisable, magic, though curtailed in scope, still stands exactly where it did We no longer consult witches, but how many otherwise intelligent people buy and wear amulets against rheumatism, mumble some magic formula to the new moon, and read with avidity those astrological prophecies in the Sunday papers, which though shorn of all pomp and beauty remain in essence identical with their sixteenth century prototypes

Artificial Pneumothorax

Its practical application in the treatment of pulmonary tuberculosis Editors EDWARD N PACKARD, M.D, JOHN N HAYES, M D, SIDNEY F BLANCHET, M D London Henry Kimpton Pp 300 21*s*

MUCH has been written about therapeutic pneumothorax, but this book is a valuable contribution, coming as it does from the pens of seventeen Saranac Lake physicians Pooling their experience, they have produced a practical guide to treatment by artificial pneumothorax which embodies the practice of the Trudeau Foundation Much of what they say has necessarily been said before, and is familiar to specialists in this country, there is nothing new, for example, in the historical survey, admirable though it is, or in the chapters dealing with apparatus and technique The physiology of pneumothorax and the pathology of the collapsed lung are given their proper share of space, and the value of the X-ray picture in the control of treatment is clearly set out Dr H L Sampson makes the captivating statement that "the X-ray is not the handmaiden but the mistress of therapeutic pneumothorax" The best wine, however, is served towards the end The chapters by Dr J N Hayes on pleural complications of artificial pneumothorax and by Dr W W Woodruff on the results of treatment of tuberculous empyema, are very good indeed Their practice is neither too conservative nor too energetic, and their opinions are constantly backed by results Finally, in the last chapter, Dr Hayes and Dr Packard discuss the results of treatment by artificial pneumothorax In this assessment they use the findings of others as well as their own, and handle an almost impossible task adroitly The book does not set out to be a symposium, but leading references are given at the end of each chapter

Your Health in Wartime

CHARLES HILL, M D Camb, D P H London University of London Press Pp 48 1*s*

THIS little book is based on a series of broadcasts to schools arranged by the Central Council for Health Education and the Central Council for School Broadcasting, and given by Dr Hill, chairman of the emergency committee of the former body The talks are admirable, both in matter and manner, emphasis being laid on the public duty as well as the desirability of healthy life and practice Dr Hill's maxims will stick in the mind

> It is bad health as well as bad manners to cough or sneeze into the air
>
> If you feel a cold coming on get as far away from everybody as you can The person who carries on at school or work despite a cold is not a hero but a danger to the community

The first two chapters, dealing with germs and the body's defences (including immunisation and inoculation) contain much scientific information written in a simple, racy style which would interest any intelligent elder schoolboy or girl These are followed by talks on cleanliness, ventilation sleep and rest, and a supplementary chapter on food The virtue of moving as contrasted with stagnant air is made clear by explanatory examples, and advice is given on the importance of early sleep and regular habits The food section is perhaps more valuable to parents than to children, and the whole book may well be read and kept for reference by anybody interested in the care and welfare of young people

THE LANCET

LONDON SATURDAY, SEPTEMBER 27, 1941

THEN AND NOW

THEN was in 1935 in those easy ante-bellum days, when shops competed for the privilege of selling one a Polish egg and 'rationing' merely conjured up vague memories of 1917 or started mother off on a well-worn trail of reminiscence. In those days of plenty, six years ago, 63 men and 63 women of the English middle classes weighed all the food that they ate for a week of their busy lives and sent the results to Dr WIDDOWSON. It all seemed rather a bore no doubt, but Dr WIDDOWSON was enthusiastic and persuasive and the doubters were induced to participate by assurances that this was an altogether novel method of making a dietary survey, and that the results would be of far more value than any hitherto obtained by the hackneyed and inaccurate "family" technique. It seems like a dream to us now—the butter and jam these men were eating, and the meat! Two men had more than 24 oz of butter a week and four more than 60 oz of mutton and beef. The women were not quite so rapacious, but 59 of them were eating more butter than the paltry 4 oz a week allowed us by Lord WOOLTON in spring 1941.

These are some samples of the information which Dr WIDDOWSON and Miss ALLINGTON have set out on another page. They aimed at finding out how well (or ill) people were adapting themselves to the rationing and restrictions in operation during the spring of 1941. To this end they reanalysed the data which had been collected by one of them in 1935. This told them how much of the foods which were rationed in 1941 were being eaten by men and women in 1935. They then carried out another dietary survey on 57 individual women, 7 of them victims of the previous experiment. This made it possible to trace the effect of the war on consumption of both rationed foods and foods which were not officially rationed but were in short supply. Some of their conclusions are illuminating. They think, for instance, that the shortage of cakes and biscuits is due more to increased demand than decreased supply, and the Ministry of Food agrees that this is probable. They show that the women surveyed in 1941 were rapidly eating up stores of jam which they must have been accumulating before rationing started. From the study of sugar consumptions they suggest that these women were planning to replenish their stocks of jam to the best of their ability when the fruit season came along. They demonstrate how the fruit shortage had reduced the intakes of vitamin C, and point out that the majority of women in this country must have been having less vitamin C in 1941 than many of the experts have considered to be a woman's minimum requirement, and naïvely suggest that since there have been no outbreaks of scurvy there may be something wrong with the experts' computations. One of the most interesting findings was that rationing may and does restrict the intakes of the foods which fall under the official axe, but it stimulates the consumption of those which do not, so that the calories remain much where they were before the limitations were imposed. This principle it seems, was first established by McCANCE and WIDDOWSON in an experimental study of rationing, so far unpublished. Further studies of individual intakes might be of considerable benefit to the theory and practice of rationing and to nutrition in its wider aspects. Men, it appears, are likely to have been much harder hit by the rationing than women, and it is to be hoped that Miss WIDDOWSON and her colleague will now turn their attention to the sterner sex and see how they are getting on when it comes to the spring of 1942.

WHITHER PHARMACOLOGY?

THE frontiers of pharmacology are less clearly defined than those of any other subject in the medical curriculum, and therein lies its strength and its weakness. Pharmacologists as a class are imbued with an expansionist philosophy of a benign type. Their researchers—the mechanised columns of scientific thought—are often found in the adjoining territories of chemistry, physiology, bacteriology and toxicology, not to mention the lightly tilled terrain of therapeutics. It is scarcely surprising that they have had to contend with invasion by the same technique. Thus it comes about that researchers in kindred subjects find themselves operating behind one another's lines. Only those afflicted with the Teutonic plague of rationalisation will see in this organised disorder anything unwholesome, for it is one of the traditions of British medicine that the trained researcher should be allowed to flit where fancy beckons. Nevertheless, the integrity of pharmacology is seriously threatened; there are signs of impending dissolution, and already clamant voices are demanding a share of the spoil.

The science has passed through several phases since the middle of last century. Early pharmacology, as Prof J A GUNN pointed out in his Dixon memorial lecture[1] concerned itself with the investigation of the action of drugs, mainly plants and inorganic compounds, which had been empirically introduced into therapeutics. This naturally led to the investigation of other substances, and so to the synthesis of new compounds which pharmacological investigation might show to have therapeutic possibilities. The commercial significance of this development has become increasingly apparent, and it is not surprising to find manufacturing chemists paying more and more attention to their research laboratories.[2] A vast amount of work is done there, but inevitably only a tithe of it results in the production of new remedies; and an organisation must possess considerable financial resources to meet the heavy cost of research on these lines. For many reasons—monetary considerations not least among them—few universities could hope to adopt the same methods even on a small scale. The academic pharmacologist had therefore to reconcile himself to the loss of this province of his science. But no-one will deny that the work in many commercial laboratories is done with great skill; again, many firms expend large sums on fundamental research without hope of immediate reward, thus adding to the general corpus of our knowledge of pharmacology; and lastly, the universities can adapt themselves by training young pharmacological specialists to undertake research in commercial laboratories A peripatetic correspondent can see no reason for the great gulf fixed between the university and the commercial firm in Britain He would like to see something of the cooperation between the two which is customary in Germany and, he might have added, in Holland, Denmark and the United States Full-time members of the medical departments of our universities are forbidden to help a commercial firm with its research, for this is classed as private practice , yet drug firms of repute need to assure themselves that their products are non-toxic to human patients, and some products, like liver extract, must be tested on patients When a university department does such testing it may take no payment, though the firm may send free supplies of drugs in return or even pay the salary of an assistant engaged on *another* task, so potent is the fear that if the firm pays the laboratory piper it will soon call the tune of university policy If ever there was a case for open and full cooperation here is one

---

[1] *Proc R Soc Med* 1941 34 469

[2] Astonishing evidence of this is provided in the 1289 pages of The Extra Pharmacopœia the 22nd edition of which is reviewed on p 370

How to train a man to be a competent pharmacologist is disputed, but it is certainly not enough merely to take a physiologist and encourage him to use drugs for his animal experiments " The primary aims and outlook of pharmacology," says GUNN, " are so different from those of physiology that they can best be regarded as separate disciplines requiring separate direction and accommodation " It is reasonable to add that this separate pharmacological outlook can best be acquired by insisting that after graduation the aspiring pharmacologist should spend two or three years in the wards of a hospital, for these surroundings will make him more acutely aware than any laboratory of the needs of the therapeutist That the basic technique of experimental physiology and of experimental pharmacology have much in common cannot be denied, but the pharmacologist must always remember that such methods are only a means to an end—improvement in medical treatment The fetish among young researchers of " getting something published," doubtless accounts for some of the uninspiring contributions which reveal an outlook limited by the kymograph Prof RALPH STOCKMAN used to impress on his assistants the importance in research of " starting with a disease," and the advice was never more sound than it is today Its importance lies partly in committing the pharmacologist to work in the clinical field, and this means that the experimental technique of the laboratory takes second place as the occasional aid to the clinical approach Few are competent to grapple with the cause and cure of a disease, but the pharmacologist whose foremost consideration is the study of a drug or a series of drugs at the bedside will get useful data as readily as the experimental worker in the seclusion of the laboratory , and he stands to get a great deal more information that has a practical application As Sir THOMAS LEWIS says, there is still a great deal of work to be done in assessing the value of remedies in common use, and in providing a clinical justification for the use of drugs whose inclusion in the pharmacopœia depends solely on empiricism Even this kind of research serves to illustrate the importance of making a disease the starting-point of investigations on the actions of drugs If the result is the negative one of discrediting a drug previously considered effective the work is none the less valuable, for such information is c the necessary preliminary to constructive contr butions aiming at the eradication of disease

The necessity for preserving the integrity of clinical pharmacology can best be sustained from the standpoint of teaching There is now an unmistakable tendency in the schools to dissociate " pure " pharmacology from its clinical application This is defended by urging that systematic instruction on medical treatment should be postponed until the student is in his final year, and it is made an excuse for handing the teaching of pharmacology to those who are nothing more nor less than experimental physiologists GUNN, remarking that the proposal to include pharmacology as part of physiology is no novel idea, goes on to say that it has been put into practice repeatedly " and with almost uniformly bad results for pharmacology and for the medical student " This fantastic experiment seems in fact to be designed to discourage the student from taking an intelligent and critical interest in the treatment of sick people during the first two years of his clinical career As for the teaching of pure pharmacology GUNN says, " I am convinced, from long experience as a teacher and examiner, that the attempt to teach pharmacology to the medical student as a pure science and without continual reference to the therapeutic application of drugs is doomed to failure " In short, the clinical application of pharmacology must be hammered into the student from the very beginning , and it is regrettable that clinical teachers do not combine more closely with their full-time academic colleagues by introducing more pharmacology and therapeutics into their bedside teaching In most teaching units it should not be difficult to find a member of the staff who would make it his business to quiz the students on pharmacological subjects which have a bearing on cases under discussion It would be profitable for the students and now and then might even stimulate a young physician with a bent towards clinical research to approach his task through the medium of pharmacology

THE SPRAY OF DROPLETS

IF William Shakespeare had been more health conscious he might have told us that some are born to sneeze, some achieve sneezing, and some have (other people's) sneezing thrust upon them And as he had read the essays of Michel de Montaigne he would have known that the third group have nothing to fear, for the breath discharged from the head is blameless—which explains the *sois béni* ! to the sternutator But that is not at all the burden of a study from the National Institute of Medical Research, printed on another page Flash photography has established that a single sneeze may project at least 19,000 droplets a horizontal distance of three feet, and that many of these droplets may remain suspended in the air for more than a quarter of an hour Most of them, no doubt, carry only harmless saprophytes from the saliva, but one of the photographs shows potentially dangerous nasal discharge being projected forward by the blast from the mouth The range of hazard rarely exceeded six feet from the muzzle of the sneezer but in the home and workplace that range may often include a number of victims if the droplets are infective The object of this particular inquiry was o determine the relative merit of the methods in ommon use for defence against the spray Sneezing nto a coal or gas fire may be bad mannered but is ughly efficient The skilful use of a large handkerhief is hardly less efficient and few droplets get past he cheap plastic mask provided for use in shelters A gauze mask is all right once, but soon gets messy The hand however is little more than a polite gesture and is miserably inefficient The experience thus gained is timely and may well afford the basis of a hygienic code for the coming sneezing season Some of the photographs are, in fact, likely to appear shortly in a Ministry of Health "Shield that Sneeze" campaign

But one may ask why not go one better and abolish sneezing? The culprit may reply in dictionary language that it is an involuntary reflex respiratory act or, briefly, that he can t help it The one may be true and the other a half truth if that For momentary firm pressure on the nose with finger and thumb just below the bridge will completely inhibit a developing sneeze That is the safeguard of the burglar and of the surgical patient with stitches in his belly wall But avoidance of capture and of acute pain are stronger motives than social decency and the common sneezer may be unwilling to forgo the organic pleasure of the completed act Nature too must set value on the maintenance of the respiratory fairway or she would not have devised so explosive a sweep But that does not justify doing one's toilet in public Those of us who witnessed the decline of spitting a generation ago need not despair of a similar revolutionary change of public habit Before that crusade started Canon Rawnsley described the pavement outside a Lancashire mill just after closing time as like an April shower. But the reforming spirit, aided by an occasional substantial fine, has abolished public spitting and children now go to the Zoo to see the llama do it Let us then cease to regard sneezing as a rather poor joke and make a careful study of its natural history and ethic in the hope of eliminating yet another of our avoidable ills The Hampstead Institute has made a good start

Annotations

WHEATMEAL BREAD OR MILK?

It is good of the cow to help man by spending so much of her leisure in turning grass into milk, for the human body does not possess a rumen equipped with a large population of micro-organisms willing to assist in the breakdown and assimilation by their host of cellulose and other fibrous materials, whereas any baby can digest cow's milk But Mr Norman Wright, D Sc, in an interesting paper[1] from the Hannah Dairy Research Institute at Ayr, would let the cow, rather than man, consume the branny and more nutritious portion of the wheat berry as well as the grass He believes, after making extensive calculations, that it would be false economy to make an 85% extraction loaf by diverting wheatfeed from the dairying industry Sharps, pollards, wheat germ and bran will, in fact, benefit man more if he gives them to the cow and demands milk in return than if he adds them to white flour and tries to digest them himself

Dr Wright's case rests on the assumption that if you give the cow an extra 700 000 tons of wheat offals (which is the total amount of wheatfeed that would be lost if there was a complete turnover to the 85% extraction loaf), you get back 350×10^6 gallons of milk, or (say) a 25% addition to the present national supply, this is clearly implicit from the caption "resulting loss of milk" in his table 2 But is this indeed the case? Is the cow a penny-in-the slot machine into which you insert a production ration of any given size and automatically get back the exact equivalent of your feeding stuff as milk? We ought to remind him that even in peace time when we had in effect all the concentrates we needed—the wheatfeed from 73% extraction, plus millions of tons of imported wheatfeed, plus quantities of imported maize and other cereals—we only managed to get a bare 12% more milk than we did in 1940–41 It seems to us that Dr Wright's thesis—viz, that 700,000 tons of extra wheatfeed would produce an equivalent quantity of extra milk—will only be true if all the dairy cows to which the feed is to be given are on a bare maintenance ration to begin with This is not the case To assume that it is so is to neglect all the evidence of the extent to which the dairy farmer has been making himself self-supporting for the coming winter Dr Wright states "Wheatfeed is practically the only cereal product available in large volume to supply the carbohydrate-rich portion of the rations of milking cows" He is either unaware of, or has not considered, the large quantities of oats, "dredge corn" and other cereal grains which have been harvested very recently, much of which, excepting of course the millable wheat, the farmer will undoubtedly use as *food for stock* The portion of the oat crop, for example, that is required for human food and for feeding essential horses is only a small fraction of the total oat harvest, the very large remaining bulk can, and on very many farms will, be used for feeding dairy cows But even if, for the sake of argument, we went without the bread and the extra milk were actually produced there is still an economic difficulty, on which Dr Wright has not touched To put it colloquially, can the baker say to the housewife, "I'm sorry, you will have to manage with a loaf of bread less this week and you will be able to save the 4½*d*, but you can, I believe, get the same amount of energy, if you need it, from Universal Dairies next door, by buying four quarts of milk—only this will, I am afraid, cost you 3*s*"? And the answer is, he cannot

The short reply to Dr Wright's ingenious thesis is this We *must* have the extra bread, and the loss of wheatfeed for dairy cattle this winter will be more than made up from home-grown grain

PROSPECTS IN NURSING

The shortage of nurses is partly due to doubt in the minds of possible candidates about the opportunities and financial security which her profession opens to the trained nurse Some of her prospects were outlined at the conference, arranged by the Birmingham and Three Counties branch of the Royal College of Nursing, which was held at Birmingham from Sept 18 to 21 The chair at the meeting was taken by Miss Mary Jones president of the Royal College of Nursing, and the speakers dealt in turn with the outlook for the trained woman in hospital nursing and administration, as a sister tutor, in public health nursing, Queen's nursing, district midwifery, industrial nursing and dietetics Mental nursing and private nursing were not mentioned The attachment of the speakers to their work appeared strikingly in what they had to tell, it was equally remarkable that when they spoke of remuneration some were almost shamefaced at having to quote such low figures, and one or two, almost apologetically, asked their hearers not to accept less than a given—extremely low—standard of reward, lest they should prejudice the chances of their colleagues Few could claim that the posts they were describing were pensionable It is characteristic of nursing at the present time that the satisfying quality of the work is only appreciated by those who are practising it, for many of whom it completely outweighs poor terms of service But to the onlooker and the possible candidate the attractions of the work are obscured by thoughts of financial stringency and of teasing personal restrictions When Miss Edith Cockeram spoke of the ward sister's post as being one of the happiest a nurse ever holds she was speaking of this professional happiness which cannot be appreciated from without When Miss M A Carr described the work of a sister tutor as "interesting, arresting and fascinating" she was not exaggerating, she was giving a piece of intensely vivid autobiography Miss I H Sinnett showed the wide variety of social work open to the public health nurse, who can become a health visitor, a school nurse, a district nurse, or can specialise in the care of tuberculous or mentally defective patients In some areas, on gaining her public health qualification such a nurse can hope for a salary of £255 a year rising to £390, but this figure is exceptional, the maximum may be only £280, with an extra £20 if she becomes head of a home These are not brilliant prospects for a woman who has taken at least three years of general and one year of special training, yet some nurses have accepted such posts at salaries of less than £250, because they found it convenient to their own plans to do so, disregarding the effect such undercutting must have on the prospects of others The posts are pensionable, however, and also give opportunity for an ordinary home life That this is as important to those within the profession as to those considering it was also indicated by Miss M E Melville who numbered among the advantages of life as a Queen's nurse the opportunity to live and work in what district she chose, more—she can either live at the nursing association, or make a home for her family, or even share quarters and work with a friend The same enthusiasm for freedom animated Mrs Dowson-Weisskopf who spoke of industrial nursing as an opporsunity for the nurse who was something of a rebel and teformer, provided that she also had the tact of the serpent and the dove combined. Yet she had to urge her hearers not to accept salaries of less than £200 a year The dietetic nurse, whose work was described by Miss E E Richards, also had a keenly interesting job and takes a difficult course of training Is it possible that a profession offering such exceptional opportunities for wide and enriching experience has become a last resort among callings for women? The leaders of the nursing profession can fairly claim that they have everything to offer to incoming candidates a job worth doing, to hospital authorities the help they need to carry on their work But the candidates will not come without better terms of service. Dame Ellen Musson, who spoke of the past achievements of the College of Nursing in mending the nurse's lot, would perhaps have roused even more enthusiasm if she had disclosed a College campaign for the future—a five-year plan, say, in which the prospects of the trained nurse were to be raised to a level worthy of her work The shortage of nurses is the measurement of the need for this reform, and gives the College an argument which cannot be ignored

TISSUE AUTOLYSIS AND SHOCK

THE custom of wearing black at funerals derives, they say, from an attempt to propitiate or escape the malevolence of the dead spirit Superstition dies hard, even in the scientific sphere The baleful influence of the dead we translate as "tissue toxins", these we held responsible for the curious state of "shock" until the work of Blalock in America and Slome and O'Shaughnessy in this country convinced us that a major part in the production of at least some kinds of shock was played by a loss of circulating fluid into the injured part Repeated attempts have been made to demonstrate such hypothetical tissue toxins, particularly often (and with strikingly contradictory results) have liver autolysates been injected into the peritoneal cavity It is almost impossible, as Professor Florey and his associates[1] point out, without the most rigid precautions, to avoid contamination of these autolysates with saprophytic anaerobes However, with very special attention to the details of their technique, in 4 rabbits out of a total series of 96 they achieved this end, since instead of the rabbits dying after the intraperitoneal injection of 10 c cm of fresh-ground liver they survived These animals developed a transitory hæmoconcentration of + 30%, indicating a local loss of plasma, which was confirmed in other animals by an intravenous dye method The significance of this is unknown, since in one of two control animals, subject to no more than preparation and ether, a similar figure (+ 26%) was obtained Eleven out of twelve previous reports on this subject have been concerned mainly with dogs Trusler and others[2] produced sterile exudates in survivors by autoclaved liver autolysed in the presence of bacteria Their very careful work suggested, first, that the organism, harmless if injected alone, produced fatally toxic products in the presence of dead liver, and secondly, that necrotic liver alone had no such fatal effects The Oxford workers' data appear to confirm this, and in addition they report some ingenious experiments completing the picture, where acriflavine in the digesting liver autolysate prevented bacterial growth This brew resulted in survival after injection, whereas the control rabbits without acriflavine died No control experiments, however, are reported in which acriflavine was added to the autolysate just before injection The bearing of this type of experiment on human lesions has been discussed by Boyce and McFetridge[3] Minor degrees of renal damage should be looked for in all cases of presumed liver trauma, since in several cases severe cortical necrosis has supervened But it is doubtful whether deductions about types of human shock other than those associated with liver damage are at present warranted

ENDOMETRIOSIS OF THE LUNGS

OF the several theories cited to account for ectopic endometrial tissue, such as that of Sampson who postulated tubal regurgitation as the cause, the congenital theory, and the serosal theory, there is only one that really accounts for distance endometriosis and that is the metastatic theory of endometrial embolism, venous or lymphatic The authenticated cases of endometriosis found in the thigh and the brachioradialis muscle can only be explained on the grounds of venous metastasis But experimental work is still needed to demonstrate that endometrial emboli are capable of being transported in the venous system and can survive in their new habitat The theory could become even more attractive if in their new situation they could be shown to obey the cyclical stimuli of the endocrines that influence their parent tissue This work has now been successfully performed by Hobbs and Bortnick[4] They prepared the endometrium of large rabbits by injecting œstrogens and then removed it by abdominal hysterotomy Small endometrial clippings were then injected into the ear vein with a large needle, and they comment on the large pieces that they were able to introduce without ill effects on the rabbits But of 12 rabbits so operated on endometrial implants were demonstrated subsequently in the lungs of 8 Excellent microphotographs show endometrial tissue in the lung vessels and in some of these the endometrium has disrupted the wall of the vessel and started to invade the adjacent parenchyma of the lung

[3] Boyce F F and McFetridge E M *Ibid*, 1937 34, 977

[4] Hobbs J E and Bortnick A R *Amer J Obstet Gynec* 1940 40, 832

Next, Hobbs and Bortnick impregnated some of the animals that had previously been given endometrial implants in order to ascertain if a decidual reaction occurred in the ectopic endometrium in the lung In several instances this could be demonstrated, and their microphotographs clearly show a decidual reaction In control pregnant rabbits no decidual reaction could be seen in serial section of the lungs In a final experiment they tried to stimulate the ectopic endometrial tissue in the lung with stilbœstrol, and in 4 out of 12 experiments a diffuse endometriosis was produced This work, if confirmed, proves that endometrium can be transported to distant metastatic foci by the veins, that it can live in its own environment, and that it is capable of undergoing the same changes as its parent tissue under the stimulus of the various internal secretions Hobbs and Bortnick carry their argument a step further and suggest that some obscure benign and malignant tumours of the lung in women may be derived from a metastatic endometrial implant, but so far a study of 33 primary lung tumours has failed to demonstrate endometrial tissue

THE ELECTRO-ENCEPHALOGRAM IN EPILEPSY

THE discovery that epilepsy is associated with paroxysmal outbreaks of high voltage in electro-encephalographic records opened up wide fields for investigation The sequence of these waves whether rhythmic or random, their constancy, their dominant frequency, their voltage, the percentage of time that they occupy on the record, the type of wave, the number of waves in each paroxysm, their localisation on the cortex, whether discrete, bilateral, multiple or diffuse must all be considered Further studies would determine the effect upon them of physiological events, of pathological states, of drugs, of special diets and of hyperventilation, and endeavour would be made to correlate the findings with various types of epileptic attack and mental states associated with epilepsy The field is an enormous one and a mass attack has recently been made into it by Jasper and Kershman[1] working at the department of neurology and neurosurgery at McGill University, Montreal These authors present interseizure records of 468 epileptic patients They divide the high voltage waves into random waves and paroxysmal rhythms, and suggest further subdivisions of these two great groups according to shape, pattern and frequency From the point of view of localisation they classify their records into three groups the localised unilateral cortical, where only a discrete area of the cortex is involved (50% of their series), the bilaterally synchronous from homologous areas of the cortex (35%), and the diffuse (15%) They find that the great majority of the localised unilateral cortical group have, in fact, fits with a focal onset, and this is especially the case with certain types and frequency of wave In these cases a family history of epilepsy is uncommon Operative procedure should be carefully considered and pneumoencephalography will often help in the decision Slow bilateral synchronous waves occur in patients who lose consciousness at the onset of their attacks, whether petit mal or grand mal, the fits usually begin before adolescence and are called idiopathic The origin of the waves is presumably deep-seated Rather more frequent (6 per sec) bilateral synchronous waves, usually bifrontal or bitemporal, are often associated with psychomotor attacks These are the waves which are sometimes discovered in non epileptic behaviour-problem children Diffuse waves are usually found in patients subject to major fits without focal onset As a generalisation, therefore, the pattern and localisation of the waves bear a close relation to the type of fits

The real trouble with mass interpretation of electro-encephalograms is that there are so many variables to be considered In classifying the epilepsies the clinical variables require painstaking observation and on the side of the electro-encephalogram the polyglot of frequencies encountered, their size, shape, number and combination call for an equally experienced and conservative analysis When the difference between the "between seizure" and the "seizure" record of the epileptic is considered it is not surprising that workers have mainly concentrated upon the distinct wave forms encountered during clinical and subclinical fits In this field the greater part of the work of Gibbs and Lennox[2, 3] stands unchallenged as the classical reference point in the modern study of the epilepsies Their correlation of the distinct patterns encountered in grand mal, petit mal, the petit mal variants, and in the jumble of the psychomotor epilepsies forms a basis for exact clinical diagnosis Grey Walter[4] approached the subject from the other side, and studied the position of foci of abnormal waves in the between seizure records of epileptic patients. He was able to show the relationship between the clinical pattern of attacks and the focus of abnormality, with McKissock he later showed that surgical removal of areas of focal abnormality did not benefit the patient, but that in fact epilepsy is a disease of the hemispheres as a whole The biochemical approach to the epilepsies which has been made through the medium of the electro-encephalogram by Lennox[5] and his co workers, Williams[6] and others points to an underlying metabolic abnormality which may explain the relative unimportance of focal abnormality in the treatment of individual cases Jasper and Kershman have done well to correlate so many data, and have added to our knowledge, but a final synthesis is not yet in sight

SEX GLANDS AND BLOOD-PRESSURE

TWO sets of facts are combining to direct attention to a possible influence of the gonads on blood-pressure On the one hand are the well-known observations on the effects of adrenaline and pituitary extract in both man and animals, the low blood-pressures in Simmonds s and Addison's diseases and the high ones in basophil tumour of the pituitary and cortical tumour of the adrenals, the high systolic with low diastolic pressure so often found in Graves's disease, and a host of other observations linking blood-pressure with the endocrine system in general On the other hand is the rapidly growing pile of observations linking the glands of the system so intimately with each other that diseases of single glands are hardly recognised and the term polyglandular syndrome has lost all meaning, since almost all glandular syndromes are "poly" Added to these general signposts are a few somewhat vague clinical observations, some of which have been misunderstood Thus the frequent appearance of high blood-pressure at the menopause has been attributed to a deficiency of œstrogens, whereas the increase of pituitary basophil cells and adrenal cortical hyperplasia which occur at this period in animals make it much more likely that one of these glands is responsible This supposition is supported by the observation that menopausal hyperpiesia in women is more common when symptoms suggestive of Cushing's syndrome, such as adiposity, hypertrichosis and carbohydrate intolerance, are also present This type of high blood-pressure so often returns spontaneously to normal that it is difficult to assess the value of œstrogen treatment Nevertheless, such treatment is rational, and until there is evidence of its uselessness it is clearly justifiable to exhibit œstrogens with a view to shortening the hyperpietic period and possibly of preventing the permanent changes which often occur There have been reports of small numbers of patients no of menopausal age whose blood pressure has fallen after the administration of œstrogens, for instance by Gurdham,[1] but faced with many contrary experiences, such reports are bound to be unconvincing in the absence of full investigations and adequate controls The situation of male hormone therapy is still less satisfactory Steinach has long held the view that its rejuvenating effects, the existence of which is disputed by most observers, are due to widespread hyperæmia With Peczenik and Kun [2] he claimed to have produced lowering of the blood-pressure in 39 out of 49 male hyperpietics Their results were immediately challenged by Greene [3] who published accounts of a series of carefully investigated patients whose hyperpiesia had been unaffected by doses of testosterone propionate far larger than those used by the earlier observers That the question cannot be left there is shown by the later claim of Edwards, Hamilton and Duntley,[4] who not only confirmed the increase in arterialisation claimed by Steinach but obtained amelioration of symptoms in three cases of Buerger's disease and four of arteriosclerosis It seems probable that the good results of treatment with male hormone, if ultimately confirmed, must depend on the degree of irreversible change which has previously taken place in the arteries, as well as on the initial cause of the high pressure In considering the latter, the work of Selye [5] and others on the nephrotrophic effects of testosterone and androsterone may well be significant

FOR THE MERCHANT NAVY

THE controversy in the *Times* following Lord Marchwood's proposal in the House of Lords on Sept 10 for a royal commission to inquire into conditions of service in the Mercantile Marine is on the familiar lines of the controversy about state medical service But even if some of those who would like a commission are aiming at a national service they would probably leave the running and upkeep of the ships in the hands of private owners and would make a national responsibility only of the entry, training, supply and appointment of officers and men There would be Government training and instructional establishments to supply young officers for the Merchant Navy exactly as in the Royal Navy The personnel might stick to one shipping company for life, but they would be Government servants with a scheme of promotion, partly by service and partly by merit, with regular leave, retiring pensions and unemployment benefit The conditions would be not unlike those in the public health services where the personnel are employed, with variations from the national mean, by local authorities From the Speech from the Throne at the opening of Parliament in the autumn of 1936 we learned that the Government were considering measures "to secure the maintenance of a Mercantile Marine adequate for the needs of the country" Thoughtful observers of conditions in the Merchant Navy (non medical as well as medical) have long been convinced that uncleanliness and discomfort have prevented many lads from going to sea In 1902 Wm Collingridge, then medical officer for the Port of London, said that the sanitary state of ships was 50 years behind that on shore Herbert Williams, W F Dearden, W E Home and Howard Jones, in our columns and through the Association of Port Health Authorities, followed his lead in demanding what Greenwood Wilson, hon sec of that association, has aptly called "slum clearance at sea," but it was not until 1937 that the Board of Trade issued instructions to surveyors which went most of the way in fulfilling the recommendations of the association for improving crews' quarters, and even then any improvement of the old vessels was to wait for convenient opportunity Would it be cynical to note that at about this time there was a serious shortage of merchant seamen? Two years later the National Maritime Board achieved a welcome agreement about cleanliness and comfort of crews' quarters, and some may claim that for this reason, amongst others, the board is well able to look after the interests of the merchant seafarer without the lead of a commission Other bodies, such as the Ministry of War Transport, are working whole-heartedly to the same end It is probable there were various persons and bodies interested in the welfare of the factory child-worker and of the prisoner before Shaftesbury and Howard focused popular attention on all the available and ascertainable facts and initiated great reforms Surely no student of history can object to a scientific and Government-sponsored inquiry into the conditions of service of an industry so vital to the nation's welfare, at peace and at war, as the Mercantile Marine?

SCOTTISH HEALTH

WITHIN the past decade there have been obvious efforts to make Scottish health reports more readable and more timely in issue The circumstances of war have diverted energies normally available for report making, and the summary recently issued in review of the period Jan 1, 1939, to June 30, 1941 is, understandably enough, but an anæmic shadow. Much of its space is given over to an account of adaptation and preparation for war, of emergency measures such as casualty hospital provision, evacuation and related problems and health conditions in shelters Some of these measures benefit the population of considerable areas, but it would have been interesting to have official information about the actual extent to which emergency hospital provision, for instance, has been used for relief of the load on voluntary hospitals or for improving the general level of hospital services when not required for the treatment of casualties, since there is a suspicion that much of it has been allowed to lie needlessly fallow When judged by the ordinarily accepted indices, the health of Scotland in war-time is perhaps no worse than might have been expected Tuberculosis has increased, and still seems to be increasing, but other infections, with the almost expected exception of cerebrospinal fever, have remained at pre-war levels The increased incidence of tuberculosis calls for administrative action and it would have been comforting to have an official assurance that specialised institutional accommodation is immediately available for every sufferer from the disease who requires such treatment The number of cases of cerebrospinal fever, not yet alarming, is a danger signal that cannot be ignored Infant mortality has increased In this matter Scotland has for long been worse off than England, and the Scottish figure for 1940, 78 per 1000 live births, is too high The summary refers to recent legislation to widen the scope of National Health Insurance, but it is a matter for keen regret that it has been thought necessary to discontinue the illuminating reports on incapacitating sickness among the insured population that have come to be recognised as a peculiarly Scottish contribution to social medicine Information on this subject would be of more than scientific interest in time of war, and it should be collected if at all possible

FIRST-AID TREATMENT OF BURNS

A H McINDOE,
M.B N Z, M S M SC MINNESOTA, F R C S, F A C S
CIVILIAN CONSULTANT PLASTIC SURGEON TO THE R.A F ,
SURGEON IN CHARGE MAXILLO FACIAL UNIT,
EAST GRINSTEAD

DURING the past year much thought has been given to the treatment of burns. This has culminated in recommendations made by the War Wounds Committee of the Medical Research Council after a prolonged survey of the results produced by various methods, under both civilian and Service conditions It is not surprising that, considering the special causes and unusual types of burns encountered these recommendations have modified established procedure, though not as extensively as many seem to believe Careful perusal of the E M S. pamphlet (343)[1] will show that coagulation therapy, far from being condemned, remains an important method of treatment particularly in the extensive burns of the 1st and 2nd degree on the trunk and extremities common in civilian life, where shock and toxæmia are liable to follow. Exception was, however, taken to its use in encircling burns of the hands and feet and in other areas of functional importance, such as the face, flexures, perineum and genitalia, where experience showed that undesirable complications might follow It was not suggested that burns of all degrees in these special areas showed equally bad results when coagulated for many have not done so, but certainly some of the more severe burns in which function has been endangered have been further compromised by coagulants

Most competent observers will agree that it is relatively easy to distinguish between a 1st and 3rd degree burn, but often extremely difficult even under the best conditions, to decide between those of the 2nd and 3rd degrees. If the surface is contaminated with dirt and oil it may be impossible to make an accurate diagnosis of any degree. This problem is much more acute at first-aid posts and advanced dressing stations, where cleansing facilities are often inadequate light is poor, and examination is perforce superficial. When the patient is admitted to hospital the degree of involvement must be determined and the appropriate treatment decided on. It is thus vitally important that first-aid treatment should not compromise hospital treatment

Experience shows that tannic acid is not a panacea for war burns, whatever its results in civil practice. It certainly takes its place, however, in the pattern of treatment which is being slowly evolved This pattern has not yet reached finality Alternative methods are still under investigation and it is not intended here to express dogmatic opinions as to their relative value The wholesale distribution of tannic-acid preparations and vital dye coagulants to homes, first-aid posts and dispensaries has, however, created considerable confusion in the minds of many as to whether coagulants should be applied as a first-aid measure or whether other dressings should be substituted. The desire to make some sort of immediate local application to the burned area is strong, and admittedly the patient may be greatly relieved thereby The ideal local application would be a quick-drying, flexible and elastic seal, incorporating bacteriostatic and anæsthetic agents It should be painless to apply, and should resist when dry ordinary handling for two to three days without renewal and during that period prevent loss of tissue fluids and the entrance of organisms into the burned area Especially, it should be water or oil soluble so that it can be easily removed at the hospital where adequate treatment of the burn is undertaken Whether coagulation should be an essential part of its action is open to question

None of the variety of suggested preparations exactly fulfils these requirements, and until the ideal substance is produced, obviously the simplest form of easily removable dressing is to be preferred One can therefore agree with almost any coagulative or non-coagulative treatment which personal preference might dictate in the case of minor burns not requiring admission to hospital. but the first-aid application of any local treatment other than easily removable dressings to those major burns requiring hospital treatment should be discouraged This is particularly true of those more positive coagulative agents applied hurriedly and inadequately over unclean surfaces in such a way as to be detrimental to the success of subsequent treatment in hospital. While there may be some disagreement between those who believe in universal coagulation and those who do not. they are united in the opinion that first-aid tanning of serious burns is a handicap to the definitive hospital treatment. because once they are applied the crust is difficult to remove.

The function of the first-aider is therefore first to distinguish between minor burns which do not require hospital treatment and to treat them efficiently, secondly to transfer major burns to the nearest hospital or burn unit as soon as possible, limiting treatment to measures of a general nature and to simple local applications, avoiding anything which may be difficult to remove

The problem is not altogether simple, for while the majority of badly burned patients can be transported to hospital within a short time, it may be days before others can reach suitable hospital facilities Thus first-aid may be required for burns at sea or in the desert under such difficult conditions that treatment considered inadvisable where quick transport is available might be desirable where there is great delay An attempt is being made to suggest a reasonable first-aid programme adequate for burns of various types occurring under varying circumstances

MINOR BURNS

A minor burn is defined as one of the 1st or 2nd degree, covering an area not greater than 1% of the total body surface—i e , an area corresponding in the adult to one side of the hand or about 28 square inches It should not involve any of the special areas already mentioned. the hands, face, feet, flexures perineum and genitalia. Shock is not in evidence and sepsis is uncommon Pain is usually severe Healing is rapid by regeneration from the undamaged portion of the skin whatever local application is used.

General treatment —If pain is not controlled by aspirin or Veganin, then morphine gr. $\frac{1}{6}$–$\frac{1}{4}$ should be given (for an adult)

Local treatment where cleansing facilities are available —Since these burns are not sent on to hospital first-aid treatment is as a rule definitive Whatever is applied should be regarded as the final dressing Some form of coagulant is therefore safe, simple and satisfactory Coagulation seals the surface abolishes pain prevents secondary infection, and enables the patient to carry on with his work within a short time.

If the burned area is likely to be contaminated, it should be carefully and gently washed together with the surrounding skin, with soap and water An application is then made of one of the coagulants in tube form, usually available at most first-aid posts, such as Tannafax, Amertan, gentian-violet jelly, or triple-dye jelly. It is either smeared directly on the burn or applied on a single layer of lint or gauze. Alternatively, the surface may be daubed with 10% tannic acid, 5% silver nitrate, or both, or painted with gentian violet 2% or triple dye (gentian violet 1/400. brilliant green 1/400- neutral acriflavine 1/1000). If tannic acid or silver nitrate is used no dressing should be applied over the burned area.

Non-coagulant dressings may also be used, such as Vaseline gauze tulle gras, Ambrine, or soft paraffin, but care must be taken to ensure the sterility of the dressings. If sulphanilamide powder is liberally sprinkled over the burn before their application the risk of sepsis will be negligible and possibly the rate of epithelialisation greater than with coagulant dressings. It is certainly true of the sulphanilamide. tulle gras, saline sequence now in wide use. Nevertheless, the coagulants have a decided advantage over non-coagulant dressings as a first-aid dressing for minor burns in that once applied they do not require renewal or much aftercare and are not so liable to contamination from outside sources

The newer preparations such as Euglamide, a paste incorporating Albucid and a local anæsthetic and the water-soluble jellies containing sulphanilamide alone or in combination with an antiseptic, have given good results but are not altogether suitable for first-aid purposes, because of their messiness and inability to remain in situ for long.

---

[1] See Lancet 1941 1, 425

Local treatment where cleansing facilities are not available.—Not infrequently, burns of this type are badly contaminated with oil or dirt, under such difficult conditions that adequate cleansing facilities are not at hand—for instance, at a thoroughly disorganised first-aid post, where the water has failed, in the desert, or at sea in an open boat. If any form of cleansing is impossible, it is foolish to coagulate a heavily contaminated burn of any type, and thereby seal up organisms on the damaged surface. In any case, the presence of oil will prevent coagulation. It might be pointed out that in the desert where mechanical transport is usually near, benzene or petrol are excellent cleansing agents, and are also practically painless when applied to injured surfaces. Under such circumstances, one of the non-coagulant dressings should be used, and if flies constitute a menace the whole area can be sealed off with a piece of oiled silk, or, if it is available, enclosed in a Bunyan-Stannard envelope. At sea, failing all else, a compress of sea water would be excellent provided it was kept wet.

CLASSIFICATION OF MAJOR BURNS

Burns of any greater extent or depth than minor burns or any burns of the hands, face, flexures, genitalia or perineum should be regarded as of major importance and dispatched to the nearest hospital or burn unit as soon as possible. As opposed to minor burns, the first-aid problem centres round the patient's general condition and the question of how soon he can be transferred. Local treatment is of secondary consideration except under unusual circumstances, and should be concerned only with the protection of the burns from further trauma and secondary infection. Major burns may be classified as follows:—

(*a*) Major burns without serious shock where transport is available. These form the majority of war burns and are easily dealt with.

(*b*) Major burns with serious shock rendering transport dangerous. There are very few cases of this type. They become noticeably fewer the greater the experience of the observer and the more prompt the transport arrangements.

(*c*) Major burns with or without shock, occurring in situations where transport is delayed or is not available. With severe shock every moment which passes before the administration of plasma or serum increases the risk to life. Hence it is better to undertake a difficult journey than to allow blood-volume to fall and hæmoconcentration to rise. Naturally these are difficult problems and much depends on local facilities, mode of transport and distance to the nearest hospital.

SHOCK

Although shock has been divided into primary and secondary forms the former is not commonly seen; if it does occur it resembles a fainting attack due to neurogenic and traumatic factors. It usually passes off quickly under the influence of rest, heat and morphine.

True burn shock (called secondary shock) has all the characteristic signs of ordinary wound shock—rising pulse-rate and respiration-rate, pallor, thirst, anxious restlessness, falling blood-pressure, and so on. It must always be regarded as serious, for it is responsible for 60% of all deaths from burns. It may appear within an hour of injury but does not usually show itself for 6 hours or more. During this time the patient feels and looks well and may even have walked several miles to a dressing station with burns of the most extensive type. This is common in Service casualties. The detection of incipient shock in such cases is difficult without hæmoglobin estimations but the possibility of its clinical development, either slowly or suddenly, must always be borne in mind. Shock results from failure of the circulation in the face of hæmoconcentration and falling blood-volume. The "trigger" which usually induces it is rapid loss of body heat from exposure to cold or further trauma to the already injured skin surface. Undressing the patient to examine the burns in first-aid posts, or any rough handling of burnt areas, should therefore be sedulously avoided. As a rule there is a relatively safe period in the first 6 hours in which the patient, though severely burned, can stand a reasonably long journey (20–30 miles) by road ambulance. There are few cases to which this does not apply. The patient may suddenly become shocked during transfer, but this is not necessarily the result of the journey. It would probably have happened anyhow. The likelihood of shock supervening rapidly may be judged from the extent and situation of the burns, but as it is dangerous to undress a burned patient, only a very rough estimate of this can be made. In general, shock is liable to be serious if more than 25% of the body surface is involved. In estimating this percentage the following table may be useful:—

	Per cent		Per cent
Head	6	Entire front of trunk	19
Both hands	6	Entire back of trunk	19
Both arms	18	Thighs	19
Lower legs	18	Feet	6

Burns of the face, precordial area and abdomen are more dangerous than those of the arms, legs or back. The depth of the burn is not so important as its extent.

If for any reason there is delay at the first-aid post and shock is feared, the pulse and respiration should be noted every half hour, and the B.P. taken as often as possible. With burns of the hands and arms this may be impossible.

GENERAL TREATMENT OF MAJOR BURNS

Pain.—All patients with major burns should receive a full dose of morphine immediately (*¼–½ gr. for an adult*). Anything less is futile and the dose can be repeated. Many patients with severe burns are not conscious of pain until the shock phase is over but moderate burns without shock are usually extremely painful.

Shock.—If this is likely to occur while waiting for transport to arrive the patient should lie down on a stretcher or cot and be covered with blankets, with hot-water bottles to keep him warm. Unless the clothing is soaked in water or other fluids it should not be removed, and then only if something warmer can be substituted. Hot sweetened drinks such as tea or coffee should be given freely. Plasma or serum injection is rarely possible or advisable in first-aid posts, and if required should be obtained by means of a mobile unit from the nearest hospital. Rapid transfer of the patient to the hospital is certainly the better plan. In the Services, all station sick quarters, many advanced dressing stations and some ships are suitably equipped for intravenous therapy in the places where delay in transport is likely. Plasma should be used wherever it is indicated. The usual preliminary dose is two bottles of dried plasma or liquid human serum given according to M.R.C. Memorandum No. 1. This may in serious cases be increased to ten or twelve bottles.

LOCAL TREATMENT OF MAJOR BURNS

Major burns should not be coagulated as a first-aid measure. The local conditions are almost always totally unsuitable for this procedure and in the majority of cases more harm than good will be done. Burns on exposed parts dispatched forthwith to hospital should be powdered with sulphanilamide and covered with a sterile towel or wet compress of sodium bicarbonate or saline. Since contact with air is painful the burn surface may be more efficiently protected with simple vaseline gauze strips or tulle gras over the layer of powder. The Bunyan-Stannard oilsilk envelope is a useful added protection during transport, and indeed may be used alone for this purpose.

The problem of the burned patient when transfer to hospital will be delayed for days—e.g., at sea, in the desert or in isolated spots—is difficult, and will depend on the facilities at hand and the severity of the burn. For the patient's comfort it may be necessary to coagulate the whole area; in which case the vital dyes or silver nitrate 10%, which are themselves antiseptic, are most suitable. It will be best to avoid an anæsthetic if possible, for this will undoubtedly increase the risk of shock. Flies will usually constitute a major danger, hence the oilsilk envelope will have considerable value. First-aid treatment in these circumstances will constitute an unhappy compromise between what is possible and what should be done.

EUGENIC STERILISATION IN WAR-TIME GERMANY

THE Eugenic Law of July 14, 1933, still holds good in Germany. This law[1] sanctioned the sterilisation of anyone likely in medical opinion to transmit severe disease of body or mind. 8 such categories were named and severe alcoholism was added to the list, but on Aug. 31, 1939, an emergency decree was issued modifying the procedure of notification and laying down that during the war sterilisation was only to be applied where the danger of dysgenic progeny is especially grave. Should the patient be impotent or nearly so, should he be prevented from producing children by being in hospital, and so on, nothing need be done. The M.O.H. has to make up his mind on this question of urgency, but the final decision is with the regional health department through which all proposals for sterilisation must now pass.

This decree, it seems, has led to some slackening of eagerness in eugenic sterilisation, although a recent article in the medical press[2] emphasises that the decree makes no essential change in the law. Some test cases are set out to impress on the reader the strict views held by the special courts. Last year, for instance, the court refused an application for the sterilisation of a 27-year-old woman with schizophrenic symptoms on the ground that such women tend to shut themselves off more and more from the outside world and are unlikely to have sexual relations. But the appeal court reversed this decision, pointing out that in women with healthy genitalia mental aversion to intercourse cannot be taken as tantamount to sterility, for in medical experience the inhibition might at any time and without warning change to its opposite.

Three appeals against sterilisation orders give an insight into the working of the courts. The first deals with an acute attack of schizophrenia in a 31-year-old clerk, who in spring 1938 showed the first signs of mental instability. In August he consulted his doctor and was admitted to hospital with the symptoms of an acute schizophrenic psychosis: sleeplessness, excitement, dissociated speech, manic behaviour and delusional ideas. There were no physical signs. He made a quick recovery, returned home and after a short convalescence went back to work in the following December. Since then his behaviour had been normal and his work satisfactory. Two of his cousins were mentally defective and his father was a schizophrenic personality. Already in September, 1938, his sterilisation had been ordered on a certificate from the hospital officer. Appeal was made on the grounds that his nervous breakdown was without lasting effect and that his working capacity was undiminished. The court ordered a further investigation in a different hospital. This second report stated that in ordinary conversation he showed no trace of psychosis, no emotional or intellectual defect. His knowledge and intelligence were good, but tests proved that he did not grasp the significance of simple fables and proverbs and could not explain the moral of a simple didactic story. There were gaps and jumps in his thinking, typical remainders of a schizophrenia, often the only apparent symptom after recovery from an attack. As no psychological or physical cause of illness could be elicited, the court ruled out any doubt about the diagnosis of schizophrenia raised by the short and relapse-free course of the illness. It was not essential to prove any mental defect when statistical and text-book evidence before the court showed that 10–20% of admitted acute schizophrenic cases were left without symptoms or personality change. The typical picture at the time of the acute psychosis, and the disorder of thought demonstrated in the test afterwards, were sufficient to justify the diagnosis. The remission after the first attack (the article adds) is just the time when a recovered patient is thinking of marriage and the risk of progeny is gravest.

The second appeal was from a patient who had since 1932 complained of increasing hardness of hearing bordering on complete deafness. On the right side loud conversation is heard only at 40 cm., on the left at 20 cm. The cause is a pathological change in the bony envelope of the inner ear in the neighbourhood of the stapes. Air-conduction of sound is interrupted, bone-conduction at least as good as normal. The plea that she can hear well on the phone is typical of the disease. There have been no signs of inflammation in the middle ear during the last six years. Otosclerosis can therefore be diagnosed with certainty. Her mother also suffers from the disease, which must be regarded as hereditary. Not only complete blindness but any disabling loss of sight comes within the meaning of the act; similarly hardness of hearing which makes employment impossible counts as deafness. The patient's appeal against the sterilisation order was refused.

The third case was one of chronic alcoholism without evidence of physical or mental damage. The patient, a 44-year-old book-keeper, underwent a "cure" in 1929. Since then he had been convicted 11 times, all his offences being caused by drink. The chronic alcoholic does not necessarily drink continually, and he may as yet show no physical symptoms of his indulgence, nor need he lack intelligence. But he is the carrier of an undesirable gene—weakness of will. Under the influence of alcohol he forgets what he owes his family and society. In spite of what he has been through this patient had not had the strength to give up drinking and carry out his duties like a healthy man. In this case, certainly the feeblest of the series from the point of view of scientific genetics, the court ruled that evidence of a family history of alcoholism was not necessary.

In England Now

A Running Commentary by Peripatetic Correspondents

THE Home Guard Medical Officers' Course lately held at Cambridge was productive of many surprises both major and minor. Among the latter was the discovery that afternoon tea is not served in Cambridge on the Sabbath. One of the pleasant surprises was the enormous usefulness of the course, which the bald syllabus had rather concealed by its copious use of incomprehensible initials, and the high grade of oratorical ability. Another was that even those of us whose limbs had lost their primal elasticity came successfully through a course which made no small calls on our endurance. It was long: it took no count of Sunday as a day of rest; but its interest sustained us so effectually that even when official lectures were at an end (and one of these began at 9.30 P.M.) we indulged in long discussions of our own (held, I must confess, in a common-room happily provided with malt liquors).

The object of the course was not so much the instruction of Home Guard M.O.s in their duties, although this was not entirely omitted, as the provision of a background which would inspire us with the urgent need for the energetic fulfilment of those duties. This background was sketched in by various techniques. We were lucidly instructed in the nature of an infantry division, its component parts and their several functions. Then the size and usefulness of an armoured division were laid before us, with full attention to its own particular difficulties, including, for example, the method of removing casualties from tanks, as well as the ways in which it was possible to compensate for the striking contrast between the highly mobile armoured vehicle and the would-be static casualty. The functions of the field ambulance were perhaps too lightly passed over and this is a point which might be elaborated in any future courses. We shall often have to make contact with such units and it would be well if we knew more about them. We were then treated—it was a treat—to a series of lectures by specialists on methods of attack and defence, including the latest information on gas warfare, the offensive use of the tin helmet, and the psychology of the German war machine. Two points were regarded as axiomatic by all speakers. The first was that invasion, including gas attack, was the logical development of the German war plan and that it was certain to occur unless a miracle happened on the Continent. The second was that, in case of invasion, the complete isolation of territorial units of various sizes for not less than seven days was to be expected. In other words, there would be no ambulance service to such units for this period. It is an important feature of the invasion picture that these areas cannot be foretold beforehand, and will not necessarily be those in which preparation for isolation has already been begun. Which areas will finally be isolated depends more on the German general staff than on our own.

Then we got down to our own special affairs. Only one lecturer, or perhaps two, seemed to have any close acquaintance with the actual problems of Home Guard medical officers or even with the possibilities of the fighting Home Guard. We listened many times to detailed instructions about the use of facilities and equipment which we are never likely to possess. We heard almost nothing of how we might best make use of the rather meagre facilities afforded us, both in the training of H.G. volunteers and in equipment. These facts made a lecture on Home Guard tactics by the commanding officer of a Home Guard battalion tremendously welcome. It was a fine lecture and was one of the four which might have been expected to obtain most marks if we had been asked to vote on them. Three others came near the same mark. One of these, and this was another surprise, was the lecture on war surgery. Many books have been written on this subject but they have not been written for us. This lecture, by a consulting surgeon, dealt with stark realities in and near the front line. We were encouraged to make known our own difficulties, and even to pass resolutions to be put before the proper authorities. We learnt much; maybe we also taught a little.

* * *

One advantage of war is the opportunity it gives us of visiting places we would never have reached in the normal course of events. Recently we have been fortunate in seeing quite a lot of Spitsbergen (or should I say Svalbard?). Although I did not get up as far as the most northerly settlement, which is on the 79th parallel 660 nautical miles from the North Pole, and in which there is a hotel for holiday-making visitors, I spent an interesting day or two in the biggest settlement a few miles further south. In normal times two nationalities lived on the islands, but they dwelt sufficiently far apart for social intercourse between the two to be almost unknown. Except for a few trappers they worked the coal which comes out of mines placed high up on the side of steep mountains 2000–3000 feet high, dropping almost sheer to the sea. The biggest mine lay deep in a U-shaped mountain between two black scars cut into its side two or three miles apart, a scar on each arm of the U. One could go in at one entrance, walk round the mountain so that one came very near the surface on the opposite side, and emerge from the other entrance at the same height but on the second shoulder. It would be an unwise thing to do, however, for I was told one would have to go on hands and knees, the mine being nowhere more than four or five feet high. Most of the mining was done during the dark winter, the work of loading the coal on to the conveyor to be stacked off the quay for shipping being reserved for the unbroken daylight of summer. This type of mining seems to be as dangerous as deep mining, the risk of gas and fire being always present, while an explosion has been known to blow a considerable chunk of mountain-side straight out into the valley.

Several of the miners had lived there for twenty-five years and the local doctor told me he knew one or two who had not been back to the homeland for thirteen years, although most of them got away in the summer for a month to get some fresh air and keep in touch with the folks at home. Many of the younger men used to go up with the idea of working for a few years to earn enough money to return home, buy a farm and get married, but often the farm of which they dreamt proved a delusion, and having lost their money they went back for another spell in the north. There is a fascination about the place and I think many were finally caught by it and decided to make it their home.

Wildfowl abound, while other local supplies of food are gull and eider-duck eggs, cod and haddock and salmon and presumably whale-meat, although I did not see any hanging up outside the houses as one does in the Faroes. They keep their own pigs, a few horses and a few cows but for all vegetables they had to rely entirely on imports. Of the birds, I saw the big glaucous gull, arctic skuas, kittiwakes, and the apparently ubiquitous fulmar; and ashore hopping about the paths and seemingly taking the place of the house-sparrow in England, were purple sandpipers. In the spring there used to be good skiing, and races down the mountain-side, but on my exclaiming to my friend the doctor that that must be the best time of year his reply was that they preferred the winter with its perpetual dark, when the ice kept any ships from disturbing them.

Of the people I met, two had claims to special distinction. One was the doctor from the settlement further north who considered he had the most northerly practice in the world. He is not long qualified and seemed to enjoy the life tremendously. The second was a trapper who came on board with some skins, a cheerful red-headed man who I later learnt had made a wonderful though unsuccessful journey of about 180 miles from West Spitsbergen to North East Land to find Nobile when he was stranded there in 1928. The fox-skins are really beautiful, most of them being white; but a few of the rare blue are trapped and fetch a big price in Europe. Polar bear and seal are also caught. Spitsbergen, land of rocky spires, with its glaciers sweeping irresistibly down to the sea, its fiords of great depth, its almost tangible silence, and its long months of darkness has a great and subtle fascination. Living was hard there, but these people gained contentment through mastering it. Some of them will have been sorry to exchange it for smoother parts.

* * *

"You know what he is doing?" said my colleague in the tone of one describing a nameless enormity, "he is advising half-a-dozen commercial firms, and I have heard he even takes a hand in the advertising of one of them!" "Why shouldn't he?" I asked. "Good heavens, man, he is a professor in a medical school and a qualified doctor. A fellow in that position should have no truck with anything commercial." I did not see this, and said so, with the result that the discussion tended towards the acrimonious. (After all, we know each other intimately.) I did agree that this kind of thing might occasionally lead to abuse, but that seemed no reason to condemn the practice any more than the existence of a few dishonest doctors can be taken as proof that all the profession is corrupt—even though some novelists may do so with impunity. I argued that if a commercial firm is engaged in any activity impinging on the field of health clearly they must have skilled advice, and many employ completely reputable doctors on a full-time basis. There are many occasions, however, when either some special problem arises or a full-time appointment is uneconomic. It is in the interest not only of the firm but of the public also that the advice they seek should be of the best quality. It is only fair that such advice should be remunerated. Q.E.D.

My colleague was unappeased, and while he was gathering breath for a counter-attack I swept on. This noli-tangere view adopted by our universities and research institutions to commercial contacts and problems has, I urged, done the country a lot of harm. In German universities they adopt the reverse attitude. For example, I met a professor of international repute working in one of the research laboratories of the I.G. Company. I was a little surprised to see him, and really surprised when I learnt he was on the pay roll for a more substantial sum than the university paid him for his chair. He spent something like three long afternoons a week in his department and the remainder of the time in the commercial laboratory. The arrangement suited both sides—the university obtained the services of a first-class man for a much smaller salary than they would otherwise have had to pay, and the company had the kudos of a professor of high standing on their staff. This case was only one of many, and I think the system was one of the chief reasons for the advanced position which German industry held in so many fields before the war. It was also the reason why they could provide so many ersatz substances to replace materials obtainable only from abroad.

I should like to see our universities setting up departments of industrial cooperation each according to its special facilities. These departments would be available in an advisory capacity to commercial firms or trade associations. Research on specific problems or the general basic problems of the industry could be carried out. Fees could be charged for advice which would be split appropriately between the university and the department staff. But perhaps most important, students both undergraduate and postgraduate would be trained in the actual problems of an industry which they would later enter. Some industries have already set up machinery which approximates to the idea in some directions at least—for example, in wool research and rubber research—but the idea is capable of much wider application. Bristol could specialise in physical problems, Manchester in chemistry, Leeds could have a department of wool technology and dyeing, Sheffield could extend its metallurgical work still further and London would be a centre for economic consultation. Edinburgh ought to be a special centre for pharmacological investigation and Aberdeen might take on the food industry. The educational pundits will raise their hands in horror at such a plan, and maintain that the sciences must stick to fundamentals and eschew practical applications. The best answer to them is Aberdeen's motto "They say, what say they, let them say." The universities can no longer dream quietly; they must adjust themselves to the impact of events. We do not need to become soulless pragmatists, but we must be practical.

* * *

Somebody remarked of Florence Nightingale that she was a sharp-tongued, fierce virago battling for reform with ruthless passion. This may be a little strong, but so was Miss Nightingale. She interfered continually with what today is described as politics and did not hesitate to procure ventilation of official incompetence, being quite unconcerned at the risk of so-called scandal. It would be interesting to trace the exact point in history which led to the perversion of her story into the mushy and phoney fiction of the "Lady of the Lamp." One thing is certain—she would have trounced those present leaders of the nursing profession who adopt the conventual vocation attitude. I know of few practical nurses who share the opinion of one of the great Dames of the nursing profession who informed her junior colleagues that they were "God's own little gentlewomen" and proceeded to warn them that any combination on their part for the advancement of professional and economic status was improper and, by inference, against His wish. The nursing profession has been in a position of increasing danger for the last decade. Today it is not only a danger to itself but to the nation too, by reason of its inadequacy in numbers and organisation to serve the expanding needs of war. The nurses, just as the doctors, can scarcely expect anybody else to put their house in order for them. What is usually called the rank and file is ready to support any strong and active lead. The pity is that those who are already in a position to settle nursing on an equal footing with other women's professions content themselves with appeals founded on a platitudinous sentiment and shy with a skittishness unbecoming to their years away from the words "salary" and "working conditions." If they would intersperse Milton along with their pious thoughts I would recommend these words of his:

> I cannot praise a fugitive and cloister'd vertue, unexercis'd and unbreath'd, that never sallies out and sees her adversary, but slinks out of the race, where that immortal garland is to be run for, not without dust and heat.

* * *

That penicillin paper made one think. What is being utilised? An ancient feud between cocci and mould, started perhaps on some dead saurian's flesh, a thousand ages ere they were to be a mammal's guests or chanced on bread of merely tertiary man? Hundreds of these antagonisms must have been formed in that fierce mycotic struggle, started not long after earth's cooling surface caught the emanation of life. Do the bigger fungi have these hatreds too? Do men who eat mushrooms not get mumps? Do blewits and bolets protect against the 'flu? I don't know that they don't. What a subject for a vast investigation, for the organisations of those princes of prescience, Rockefeller and Nuffield. "Ah, Sir, what have you? A touch of carcinoma? We'll soon put that right, but you must take a peck of common morel. And you, Ma'am, for your child's diphtheritic croup, I know an ancient enemy of this—a white mould growing on a long-cast boot." Of course, botanically speaking we shall be sinking below the level of the herbalist to that of the messy mycologist.

Letters to the Editor

MEDICAL ASPECTS OF BOXING

SIR,—Your review and annotation of June 14 on Dr Jokl's "Medical Aspects of Boxing," leave me with the impression that the writers could not have read the book with care, for the main facts on which Dr Jokl relies for his conclusions are imperfectly stated and in some instances misrepresented. Perhaps your readers will be interested to learn how Dr Jokl came to publish the results of his scientific investigations in book form.

In July, 1939, the annual conference of the South African Association for the Advancement of Science was held at East London. At one of the meetings (at which I presided) Dr Jokl delivered an address on the medical aspects of boxing. The results of his investigations and the conclusions arrived at were so important and astounding that he was urged to publish his findings in book form. The present book is the result of that request.

Since 1939 Dr Jokl has added many new facts in support of his thesis—that "in boxing the typical accidents are inherent to the sport as such and can, therefore, only be eliminated by the abolition of this sport. . . . Special consideration must be given not so much to the question of accidents which always occur during sport and recreational activities, but rather to the problem of the intrinsic dangers inherent in boxing. There is not the slightest doubt that all the educational benefits derived from boxing can be achieved equally well through sports which do not constantly endanger health and efficiency of the central nervous system." It surprises one that the common sense of the man in the street has not long ago stumbled on the discovery that boxing is inherently dangerous. The sole object of each boxer is, by all the physical force at his disposal, deliberately to inflict such injury to the head, the heart and other vital parts of the body of his opponent as would cause unconsciousness or incapacity to continue the fight. The opponent's head is the main object of attack in this so-called sport, whereas in other forms a ball is usually the concern of the contestants, and should fatal results follow they are not "deliberately" intended, as in boxing, but are accidents in the proper sense of the term.

In view of the truths that science has revealed as to the nature and consequences of the injuries inflicted and intended in boxing, our law courts will have to revise their conception of the criminal liability of the person who has caused the death of his opponent and of those associated with him. Undoubtedly, due to the popularity of this so-called sport and the rules controlling it, our courts have dealt leniently with the accused person. The doctrine of "volenti non fit injuria" was held to apply. It was however not sufficiently realised that he who deliberately causes and intends to cause an injury which probably would have fatal results should be held to be responsible for the natural and intended consequences of his act. The boxer, therefore, in future cannot escape the full implications of the law, and, what is more, those who pander to the sadistic tendencies of human nature by staging prize fights solely for financial gain should be held criminally liable as accessories before the fact or as accomplices. No-one would dream of contending that the duellist who is quick on the trigger and kills his opponent would not be guilty of murder.

In South Africa, Dr Jokl's book has been received by scientists with approval, and the only criticism which has appeared has come, as was anticipated, from persons who either make their living out of boxing or who are financially interested in this so-called sport. The facts disclosed and the conclusions arrived at have not been questioned by any scientist of standing; resort has been had to the usual red herrings—that fatal accidents also occur in other forms of sport and that none would advocate their abolition for that reason or that the research has not been sufficiently comprehensive to justify the total abolition of boxing.

It cannot be correct to assert that "fatal cases hardly ever escape public attention." The reason why the public is kept in ignorance of the great many fatal cases that do occur is very simple, when one remembers that every device is employed, especially by those who are financially interested in boxing, to uphold its popularity either by suppressing facts or by obtaining a death certificate which would preclude the necessity of a public inquiry. One can only wonder at the fact that so many fatal cases, directly due to injuries received in boxing, have received any public attention at all. Popular press reports are valueless in establishing the frequency of the occurrence of any such event.

It is satisfactory to note that your annotator admits “ that it might be wise to forbid it [boxing] to special categories of men, such as air pilots, who need all the mental alertness and neuromuscular coordination they can get.” But why confine it to special categories of men if, in fact, it is dangerous ? It may be conceded that the inherent dangers of boxing may be minimised by, for example, increasing the weight and size of the gloves, but that would be staging a pillow fight—it would not be boxing as popularly understood—and no-one would pay a large sum to witness such an exhibition, or be attracted to such a tame sport without a “ knock-out blow ” ; that is, after all, what the public come to see.

Dr. Jokl has done a great service in boldly exposing the inherent dangers of boxing, and no parent or teacher of physical training should fail to study his case-histories and conclusions.

Pretoria, South Africa. F. E. T. KRAUSE.

SIR,—I have read with interest your editorial comment on Dr. Jokl's book. Boxing is either a good sport or a bad one and I cannot make out from your annotation which category you favour. Your remark that “ it might be wise to forbid boxing to special categories of men, such as air pilots, who need all the mental alertness and neuromuscular coordination they can get ” seems to indicate that you are in favour of the abolition of this sport. I shall be glad if you will explain the reasons for this conclusion, for the critical tone of the rest of your annotation does not bear this out.

JACK PENN,
Johannesburg. Major S.A.M.C.

⁂ Boxing may be a good sport but, like love, it acquires an evil smell when it becomes a business proposition. Amateur boxing has merit in harmonising courage and self-control. As a training in self-defence boxing is popular with the police and the military. But that has no comfort for the poor loons who get punch drunk in the ring for other people's profit.—ED. L.

EXCLUSION OF NEUROTICS FROM THE FORCES

SIR,—The incidence of acute neurosis in the Services is extremely low, and the number of men who break down under the acute stress of war is very small, a fact well illustrated after Dunkirk. In almost two years 2045 Service patients have been admitted to a special centre where neurotics are concentrated, and 80–90% of these were cases of chronic neurosis which could in no way be described as war neuroses. They are the chronic neurotics of peace-time who have broken down as a result of trivial stresses, such as inability to bear Army discipline or separation from their families, and they are admitted to hospital with an exacerbation of their chronic neuroses. Some were able in peace-time to carry on in spite of symptoms ; in the Army they are unable to do so. They report sick, are seen by a command psychiatrist and are admitted for treatment. They show an almost monotonous repetition of symptomatology, and their treatment is enough to break the heart of able and experienced psychiatrists. Moreover, many chronic neurotics have an extremely bad effect on the better patients in hospital, being chronic grumblers, unwilling or unable to make any effort to return to Army life. Most of them should never have been passed by the medical boards. In addition men suffering from chronic neurosis are sometimes admitted who were doing skilled work of national importance before being called up ; they are unable to do the work in such units as the Pioneer Corps, to which they are often posted, and are admitted to hospital because of an exacerbation of their neuroses.

This waste of man-power, apart from waste of money and time, could easily be avoided. In the United States a circular has been issued to physicians of medical boards who are not psychiatrists, briefly presenting the main symptoms by which they can recognise psychoneurosis, neurosis or organic diseases of the nervous system (see *Lancet*, May 17, 1941, p. 633). Should the examining physician suspect any neurotic disorder, he sends the man for expert psychiatric examination. By this means many chronic neurotics are eliminated before they have the chance of being enlisted. If more care were taken in England at the time of medical examination (one epileptic had enlisted five times), the number of admissions to hospital for neurosis could be drastically curtailed and much trouble to the pensions authorities avoided ; moreover, psychiatrists attached to special neurosis centres would have time to act in an advisory capacity to medical boards, and so prevent this large group of chronic psychopaths—anxiety states, hysterias, mental defectives, epileptics, &c.—from being passed into the Army.

A follow-up of chronic neurotics invalided from the Army and living in the London area has been begun. It was thought that when these patients were invalided out their more acute symptoms would disappear, and this was found to be the case. In fact, they were restored to their pre-war neurotic level, and said they felt as fit as usual. Yet social workers found that some who before enlistment had had good work records were now unable to hold down jobs similar to those which they had been doing in peace-time. If this finding holds good for a *large number of cases, it provides another important* reason for excluding the chronic neurotic from the Services.

The remedies seem to me to be as follows :—

(1) That recruits with a history of neurosis should be required to produce a letter from their family doctors or a hospital stating their history, family or personal, of neurosis or psychosis, fits, mental defect or backwardness. If a man produces any such evidence or the examining doctor finds any sign of oddness, personality disturbances or psychopathy the patient should be referred to a psychiatrist, preferably one who has had experience with the neurotic under Service conditions, who will decide as to his fitness for military service. It does not follow that all chronic neurotics will be rejected —many of them are suitable for particular trades in the Army, and can release other men who are efficient fighting units. This is already being done under a War Office training scheme with many inpatients who would formerly have been invalided out. The argument that many recruits would use this letter to avoid military service is not valid, since a man bringing such a letter would be referred to a competent psychiatrist who would decide whether he was fit or not. In several cases recruits have brought letters from psychiatrists, but the letters have been ignored and the men passed A1.

(2) That all doctors on medical boards who are not psychiatrists should be issued with a circular like that used in the U.S.A., giving the symptomatology of personality defects, neuroses and psychoses concisely and simply, and also telling how to examine the patient from the psychiatric point of view, and what to look for.

Obviously such a document as I suggest must be highly confidential ; in America the contents became known and in some cases recruits anxious to avoid service knew the answers beforehand. But I believe by some such means admissions to neurosis centres could be cut down by half.

Sutton. LOUIS MINSKI.

FIRST-AID FOR EVERY SOLDIER

SIR,—Your leader of Sept. 13 has made a very sensible suggestion which is based apparently on the observations of an anonymous lance-corporal. Now lance-corporals in the nature of things have not much knowledge of the Army apart from their own unit, and would not be likely to know if other troops had received instruction in first-aid. It is a fact that in the division with which I served in France all ranks had received such instruction before proceeding overseas. I have reason to believe it is usual to give divisional troops an inkling of the basic principles of first-aid. The regimental medical officer is the man to do it, not the subaltern who already has enough on his plate. I do not think it is a good idea to hand out Mr. Keogh's cards with diagrams and brave words, however well intentioned. The soldier of today has to be approached in quite another manner which may be left to the discretion of the R.M.O., who should know the men he is dealing with.

Manchester. W. A. RAMSAY.

INTRACAPSULAR FRACTURES

Sir,—In your annotation of Sept 13 you refer to a commission set up by the American Academy of Orthopedic Surgeons, which reported bony union in 70 1% of cases of intracapsular fracture of the femoral neck treated by pinning and followed up for one year You then refer to an article of ours in the *British Journal of Surgery*, quoting our results as 58 7% bony union But close inspection of our figures will reveal that bony union did actually occur in 70% of cases followed up for one year Seventy-five cases were reviewed, but 4 died shortly after the operation and a further 8 could not be followed up either because of death from other causes, in the years intervening between the operation and the follow up, or because (in 2 cases) the patients were never traced Forty-four cases of bony union out of 63 cases is 70%

ARTHUR L EYRE-BROOK,
Bristol KENNETH H PRIDIE

SOLDIER'S DEFENCE AND PUBLIC'S ATTITUDE

Sir,—Dr Clifford Scott's paper is very interesting but a trifle vague, perhaps that is inevitable in a subject like psychology, but I feel there is excuse for commenting on some of his statements

Before the last war he says, the valorous soldier was considered to be fearless the implication being that other views hold the field now There has, of course always been a school of thought which held, and still holds, that fearlessness and courage are more or less the same thing, as indeed they are, if by courage is meant an ability to do dangerous things without being afraid, or appreciably afraid By afraid in this connexion one means something more than merely that state of mind which prompts one to take precautions There is also and always has been, a rather more subtle school maintaining that the truly brave is he who does dangerous things in spite of intense fear, and if we like to define courage in that way there appears to be no objection, provided we are consistent Thirdly, there are, and always have been (at least for many centuries), those who believe that human behaviour is determined by the ultimate laws of nature, and therefore courage is merely a convenient name for one of the characteristics of Homo sapiens You pays your money and you takes your choice of these views, according to your temperament, intelligence, upbringing and so on

The point is that, in my submission, none of them is new, and none has greatly lost favour, it is not clear that there has been anything amounting to a complete change in the public's attitude The public still believes in cowardice as it does in sin and it is likely to go on doing so, not because of the truth or otherwise of these conceptions but because they provide a practical rule-of-thumb for obtaining *certain* results Just as murderers are hung pour encourager les autres (or, if revenge enters into it that is presumably a primitive mechanism designed for the same purpose) so cowards are shot on the field of battle (and will continue to be shot, all the psychiatrists in the world notwithstanding), because it is sometimes the only way to produce the desired effect There are, rather naturally times when no milder stimulus than the fear of being shot in the back will suffice to override the stimulus of the fear of being shot in the front Doubtless in many cases the fear is not a fear of death pure and simple but of something more complicated perhaps rather of the manner of dying If I understand Dr Scott, there is no such thing as fear of the unknown, but only fear of a repetition of the known, or something like it The result is unfortunately the same in this case

Newcastle-on Tyne W E HICK

FIRST-FIELD DRESSING

Sir —Your timely and encouraging leader "First-Aid for Every Soldier" prompts me to draw attention to one pattern of first-field dressing which has been issued to the Forces

In a lecture on first-aid which I gave recently to a platoon of Home Guard I invited one of the audience to come to the platform and show us how he would apply his field dressing He stripped off the layer of Cellophane, loosened one end of the brown calico outer cover by breaking the thread which secured a flap, and withdrew one of two dressings each encased in waterproof white calico The package resembled a sealed letter-card, and nothing seemed simpler than to tear off the half-inch strip which ran along three sides However, he paused to read the instructions "Tear apart the uncemented corner as indicated by the arrow" For several minutes he wrestled with the packet, but to no purpose The corner indicated by the arrow was not "uncemented" enough Finally very red in the face, he grasped the dressing firmly in one hand and with a mighty effort managed to tear open one end of the cover The whole performance took about five minutes I later tried to open three similar packets and had the same difficulty with *all of them* I can well imagine that a soldier whose hands might be tremulous in the excitement of battle or benumbed by frost would find it utterly impossible to open one of these dressings I hope the products of other makers are more amenable

May I suggest that every medical officer in the Forces should pick at random a dozen of his men and see whether they have any difficulty in opening their first-field dressings?

STANLEY ALSTEAD
Glasgow

GLYCERIN-GELATIN BASE

Sir,—The title of our article of Sept 13 (p 329)—A Glycerin-gelatin Base for Irradiation Dermatitis and Burns—may be open to misconstruction The base for which the formula is given was first employed by me some years ago in the treatment of ordinary burns As tannic-acid jelly has been widely employed in the treatment of both thermal burns and moist desquamation of the skin following irradiation, the attempt to treat the latter condition by the glycerin-gelatin compound seemed logical The advantages claimed for the preparation have been amply demonstrated for both types of lesion

London, S W 3

BULLETIN OF WAR MEDICINE

Sir,—In your annotation on Anglo-Russian alliance in medicine (*Lancet*, Sept 20, p 344) you refer to the journal which the Tropical Diseases Bureau of the Medical Research Council has been publishing for more than a year as *War Medicine* May I remind you that the actual name of the journal is *Bulletin of War Medicine*, it should not be confused with the recently produced American publication *War Medicine* The bulletin is edited for the M R C by the Bureau of Hygiene and Tropical Diseases under the direction of Sir Harold Scott, but this bureau is not part of the organisation of the Council, and the bulletin is not concerned, except incidentally, with problems of hygiene and tropical diseases These are dealt with by the two other publications of the Bureau the *Bulletin of Hygiene* and the *Tropical Diseases Bulletin*

CHARLES WILCOCKS
London, W C 1

PLUMP TYPE OF GRAVES'S DISEASE

Sir,—I have read with much interest Dr Trotter and Mr Eden's paper on this type of Graves's disease, especially with regard to the high mortality of subtotal thyroidectomy—namely, two cases of sudden death out of seven operated on At autopsy generalised lymphoid hyperplasia was found and apparently no other cause They say in their paper "The cause of the two deaths was not apparent but since their condition deteriorated after a brief period of respiratory embarrassment these patients may be unduly susceptible to anoxæmia" Unfortunately no more clinical details were given and I wish to suggest that the patients died from interstitial emphysema and pneumothorax

This mediastinal emphysema arises from the neck incision, especially in those cases which have a drainage-tube in them and the pneumothorax is bilateral and will rapidly cause death An excellent paper on this condition by H J Barrie (*Lancet*, 1940, 1, 996) gives clinical and post-mortem details The condition will be overlooked at the post-mortem examination unless each pleura is opened under a water seal for issuing air This to my knowledge is not done usually at routine sections I believe that this condition will probably explain some deaths on the operating table during thyroidectomy, as it is overlooked in the general excitement to perform

Obituary

HENRY ASHBOURNE TREADGOLD

C B E , M D LOND., F R C P , GROUP-CAPTAIN R A F (RETD)

Group-Captain Treadgold, who died suddenly on Sept 15 in his 58th year, was the son of Dr F C A Treadgold, who practised at Southport

He was educated at Fettes, Cambridge and King's College Hospital, London, where he won scholarships and qualified in *1909*, taking the M D Lond in 1912 He acted as casualty officer at the Royal Free Hospital, medical Sambrooke registrar at K C H and assistant superintendent of laboratory at the Brompton Chest Hospital In 1914 he joined the R A M C , served as sanitary officer at Colchester, went to France with the 48th Brigade and later to Mesopotamia, being mentioned in dispatches On the formation of the R A F Medical Branch in August, 1919, he was granted a permanent commission as squadron leader After three years in the medical directorate of the Air Ministry he was D P M O in Iraq 1921–24 and then served at medical headquarters, first as president of the medical board and from 1931 as consultant in medicine until his retirement owing to ill health in June, 1936 His name appeared among the Birthday Honours that year, and in the following year he was elected F R C P

Treadgold was a man of exceptional ability who excelled in whatever he undertook, both at work and in pursuit of his hobbies—fishing and gardening He set himself a high standard of efficiency and expected it of others Logical, quick-witted and incisive, he made an ideal president of the Central Medical Board To those who worked in close contact with him he was a loyal and inspiring colleague, qualities which earned their affectionate regard The superficial attitude of indifference which he assumed concealed a sensitive nature and a kindly disposition

In 1909 he married Evelyn Diana Landor, who survives him with one son and one daughter

Public Health

From the School Reports

GLOSSOP

The chief matter in Dr Marcus Milligan's 1940 school report is the description of a new functional test for nutrition and the record of the results obtained from it The test is devised to demonstrate loss of strength and endurance by bringing into play the anti-fatigue powers of the body , it being presumed, in our opinion justly, that anti-fatigue would be the first composite function to show the effects of insufficient nutrition The original test was the length of time a child could support itself on a horizontal bar, but as this gives undue measure to handgrip and hanging power, it was abandoned in favour of pulling up a counterpoise of equal weight to the child's body Dr Milligan says that to judge the physical condition of children by any tests we must have standards and for this reason he includes standards, so far as he has been able to obtain them Since, however, the main value of the test is to show *alteration* of power, the actual standard must be that of the individual child on some given date and the test must be repeated at intervals, for it is a dynamic function which is to be measured The test has the merits of simplicity and comparative freedom from upsetting psychological interferences, and shows promise of being of considerable value

NORTHANTS

Dr C M Smith, school medical officer for the county, had three special surveys in *January*, May and *October* of the heads of native and received children The percentage of those with nits (or worse) was for natives, 4 3, 4 0, 4 6 , for evacuees, 5 5, 3 6, 5 8 The seaso variation of the natives has been usual in all parts of country for the past 30 years , the variation for evacuees is due to receiving householders being fait in cleansing their guests without realising that to k heads clean is a continuous process

Infectious Disease in England and Wales

WEEK ENDED SEPT 13

Notifications —The following cases of infectious dis were notified during the week , *smallpox* 0 , *sca* fever, 1005 , whooping-cough, 2710 , diphtheria, 9 paratyphoid, 141 , typhoid, 49 , measles (exclud rubella), 808 , *pneumonia (primary or influenzal)*, 4 puerperal pyrexia, 151 , cerebrospinal fever, 1 poliomyelitis, 36 , polio-encephalitis, 4 , encephal lethargica, 1 , dysentery, 94 , ophthalmia neonatoru 83 No case of cholera, plague or typhus fever notified during the week

The number of civilian and service sick in the Infectious Hosp of the London County Council on Sept 10 was 1279 , includ scarlet fever, 128 diphtheria, 245 , measles, 41 , whooping cou 484 , enteritis, 19 , chicken pox, 30 erysipelas, 24 , mumps, poliomyelitis, 1 , dysentery, 16 , cerebrospinal fever, 19 , puerp sepsis, 16 , enteric fevers, 40 , german measles, 2 , polio encep itis, 2 , other diseases (non infectious), 41 , not yet diagnosed,

Deaths —In 126 great towns there were 2 (1) dea from enteric fever, 2 (0) from measles, 3 (0) from scar fever, 15 (3) from whooping-cough, 22 (0) from diphthe 25 (3) from diarrhœa and enteritis under 2 years, a 8 (0) from influenza The figures in parentheses are th for London itself

Liverpool reported 1 death from enteric fever Sunderland Cardiff each had 3 deaths from whooping cough There were 3 fa cases of diphtheria at Sheffield

The number of stillbirths notified during the week w 185 (corresponding to a rate of 36 per thousand to births), including 16 in London

artificial respiration If it were borne in mind, a rapid aspiration of air from both pleuræ should save life

I have been unable to trace any cases which have been saved by this prompt and simple measure, and would like to be put in touch with any known recorded successes

City General Hospital, Leicester A P M PAGE

Dysentery in Edinburgh

A small outbreak of dysentery has occurred in part of Edinburgh and the infection has been traced to a dairy farm n the south side of the city. An order has been served on he farm to cease selling milk and butter. All except one of he households where the 25 cases occurred obtained their milk from this farm.

Chadwick Lectures

On Tuesday, Oct. 7, at 2.30 P.M., the first lecture in the 9th annual series of Chadwick public lectures is to be given t 26, Portland Place, London, W.1, when Mr. V. Zachary Pope will speak on the influence of war on surgery.

Pathological Demonstration

On Thursday, Oct. 9, at 3 P.M., Dr. W. Pagel will give a emonstration of some cases observed during the past year n the pathological department of the Central Middlesex County Hospital, Acton Lane, N.W.10.

Maternity Leave in the Civil Service

Under an agreement reached between the Treasury and he National Whitley Council, married women civil servants, permanent and temporary, will be entitled to maternity leave.

Medical Casualties

Surgeon Commander A. N. Forsyth, M.B. Aberd., R.N. and Surgeon Lieutenant R. M. Calder, M.B. Glasg., R.N.V.R., are reported to be missing, presumed killed.

Captain I. M. G. Stewart, M.B. Lond., R.A.M.C., and Lieutenant L. F. Smith, M.B. Edin., R.A.M.C., have been posted as prisoners of war.

Royal College of Nursing

The college has set up a reconstruction committee, under he chairmanship of Lord Horder, to consider the immediate steps necessary to carry out some of the Athlone Committee's reforms and to promote more advanced schemes of nursing. The British Medical Association, the British Hospitals Association, the Incorporated Association of Hospital Officers, he Association of Hospital Matrons, the County and County Borough Hospital Matrons Association, the National Association of Local Government Officers, the Women Public Health Officers Association, the Nuffield Provincial Hospitals Trust, he Medical Women's Federation, the King Edward's Hospital Fund for London, and the Society of Medical Officers of Health will all send representatives to the committee, half of whose members will be nurses representing the various branches of their profession.

Planning at Bath

Health education and finance were tackled by a conference on the reconstruction of post-war Britain which met in the pump room at Bath on Sept. 7 under the presidency of Mrs. Mavis Tate, M.P. Mr. R. S. Trueman, F.R.C.S.E., who opened the health session said that the great difficulty of our present hospital system was the provision of treatment for the middle classes. He advocated the setting up of a royal commission of five members all under 40 years of age to consider the problem. He thought we needed a regional national hospital system with each region run by a hospital officer; hospital staff appointments should be made by a board of university professors who would be outwith local politics. He also proposed the enlargement of the hospitals and the closure of all nursing homes. The hospitals would be open to everybody and each should pay what he could afford. Mr. C. E. Kindersley, F.R.C.S., though it best to plan on what we have at present and not try to sweep away the voluntary hospitals which were some of the biggest institutions in the country. Hospitalisation had to be paid for by taxation or by voluntary effort, and he thought it should be "a little bit of both." He urged the medical profession to get on with its own job—the investigation and treatment of disease and if possible its prevention—and he knew no greater damper to enthusiasm than bureaucratic control. Miss Maud Forrester Brown, M.S., contended that the voluntary hospital had often not been able to cope with the expansion of industrial populations. She urged that industry should carry the cost of the health of its population. Dr. Elizabeth Casson stressed the need for an organised mental health scheme. Mrs. Clara Cross, M.D., speaking as a mother and a doctor asked for instruction in mothercraft and fathercraft for older boys and girls. And finally Mrs. Forbes Fraser pointed out that none of these schemes could be brought to fruition without nurses. There must be a new system of training student nurses and some organisation for the assistant nurse.

Notes, Comments and Abstracts

HEALTH INSURANCE IN SOUTH AMERICA

FOR some years the South American states have been giving attention to social insurance, and important conferences were held at Sàntiago de Chile in 1936 and at Havana in 1939 which provided programmes as a basis for governmental action. Chile has been a pioneer and by its example has encouraged other countries. Its act of 1925 from the outset applied to the whole wage-earning population while other states adopted a policy of gradual extension.[1] The responsibility for the health of the workers is placed on the employers in large undertakings such as mines, forestry and plantations, who are obliged to provide first-aid, the services of one or more doctors, and some hospital accommodation, in that order, in proportion to the number of their workers. The Santiago-Havana programme emphasises the value of the preventive and curative services afforded by sickness insurance. The main purpose is "to make available to insured persons and their families the resources of modern medicine for the preservation of their health and for the detection and treatment of disease in its earliest stages." Chile took a further step forward in 1938 with the Preventive Medicine Act which institutes periodical examinations for the whole population. A complete English translation of the act with the decree which put it into operation has just been published in the legislative series of the International Labour Office. Its object is "to bring to light the existence and arrest in time the development of chronic diseases such as tuberculosis, syphilis, rheumatism, diseases of the heart and kidneys and also occupational diseases such as lead poisoning, anthrax, silicosis, ankylostomiasis." The administration of the act is entrusted to medical boards who supervise the periods of partial or total preventive rest which may be prescribed. A preventive rest day means a period equal to half the ordinary working day, and disciplinary measures may be taken by the boards for non-observance of medical directions either by the employer or the employee. Where partial preventive rest days would disorganise work they must be replaced by days of total preventive rest and pay is made up by the provident funds. The place at which the rest-cure is to be taken may be prescribed for the patient. Medical examinations must be made at least once a year, and medical boards may visit the places of work for the purpose though the examination must be made in the employee's own time except when an agreement to the contrary is made with the employer. The examination comprises at least the following tests: (*a*) summary clinical examination (weight, height, general examination, pulse, blood-pressure, auscultation of the thorax); (*b*) radiological examination of the thorax; and (*c*) Kahn or Wassermann reaction. Each board must include a tuberculosis specialist. There is a right of appeal by employers or employed against the decision of the boards to a medical complaints board consisting of medical representatives appointed by the president, the employers and the employees organisations.

The social insurance scheme of Peru has a general resemblance to the Chilean but with a novel feature. With the contributions collected from the employers and the state since 1937 hospitals have been built. The first and largest with 750 beds and the most modern equipment was opened in Lima last December, and another was opened in Ica in February. The scheme includes the provision of 12 other hospitals, 40 polyclinics, 50 rural dispensaries and 10 travelling dispensaries. Only when hospitals are available to provide the benefit within an area are the employed persons called on to make their contributions. Recent developments in the South American states include the formation of the inter-American Committee to Forward Social Security which will work in collaboration with the International Labour Office.

THE ANTISEPTIC CYCLE

IN his Honyman Gillespie lecture on Aug. 28 Sir John Fraser gave an account of wound infection before the first antiseptic era and reviewed the researches of Pasteur and Lister He demonstrated the various antiseptic materials used by Lister for compound infected fractures and quoted extracts from Lister's paper published in THE LANCET of 1867, describing the successful treatment of eleven cases of compound fracture, which might be said to mark the advent of the first antiseptic era Sir John then traced the history of the opposition which arose Critics of the Listerian principle declared that strong antiseptics were unnecessary and were prejudicial to the healing of the wound He quoted from the writings of Spencer Wells and Lawson Tait, and summarised the contentions on which the aseptic school was eventually established Ultimately a compromise was reached Except in a few centres the employment of antiseptics was reduced to a minimum, sterilisation was achieved by heat and steam-pressure The highest standard of cleanliness on the part of the surgeon and all his helpers was exacted, and chemical disinfectants were only used in situations where they were not prejudicial to material or tissues It seemed unlikely that a second antiseptic era would arise, but in 1914 the war casualties reproduced conditions which resembled those of the pre-Listerian period, and there was a renewed interest in the problem of wound infection—in other words, the advent of the second antiseptic era

---

[1] Stack, M. *Int. Lab. Rev.* July, 1941, p. 1.

Today we are face to face with the same problem Accepting the premise that all accidental wounds are infected, Sir John insisted on the importance of carrying out bacteriological examination of all these wounds as soon as they came under treatment He described and illustrated the common types of wound infection—the pyogenic, the clostridial and tetanus He drew attention to the value of tissue resistance as it develops in sequence to infection, and insisted that wound treatment must be designed to stimulate natural processes As a preliminary to treatment three considerations must be kept in mind—

1 The certainty that the wound is infected,

2 That two hours will elapse before multiplication of organisms will occur,

3 That there will be no actual infiltration of tissue by organisms until after the sixth hour.

Prophylactic serum should be used wherever a clostridial infection was suspected The sulphonamides have proved of immense value from the prophylactic and therapeutic aspects, and have removed much of the risks attendant on accidental wounds Of the depot antiseptics he favoured Albucid soluble (*p*-aminobenzenesulphonacetamide), and introduced 5–15 g of this salt into all potentially infected wounds

A FREED MAN LOOKS BACK

Jan Slomka was born in serfdom in 1842 and lived all his life in the village of Dzikow on the borders of Austrian Poland His life story, which he finished at the age of 87, personifies the struggles through which the peasants evolved to democracy (From Serfdom to Self-Government Minerva Publishing Co Pp 274 8*s* 6*d*) As a young man he was one of the few literate people in his district, and, being energetic and observant, he was able to apply new methods in agriculture which other peasants, more conservative and superstitious, refused to consider He consequently prospered and for 40 years was mayor of his village He describes the psychological difficulties the peasants had in adjusting to their freedom During serfdom they had got used to regarding work on the land as an imposition Since the land did not belong to them they pottered along from day to day When serfdom ended this ingrained habit remained like a yoke and was not shaken off for twenty years During this time they lived in extreme poverty, and being unable to see any prospect of improvement most of them turned to vodka for solace, rather than to better farming technique Land was exchanged or taken on lease, the payment being made in grain or potatoes delivered in the spring The peasant unlike the more business-like rentier, was slow to appreciate the monetary value of land, the saying was "Am I to live for ever that I should buy land outright?"

Medical services in the village did not exist, and the sick travelled miles to visit quacks who practised magic on them If too ill to travel a delegate would go to ask advice taking along the patient's shirt and a sample urine Slomka's account of malaria reads like somethi from the eighteenth century

Fever, so called "three day ague," was so common th nearly everyone took it The chill and fever wou return for an hour every three or four days—hence the nan It arose from eating unripe fruit or sourgrass, from drink beer on an empty stomach, from getting soaked through a taking cold or from overwork Only when it held on fo long time, a year or even more, and the patient got so b that he could scarce walk, would they get busy and treat with home remedies—herb tea or quinine—this latter bei the thing that helped most in such cases

Slomka's detailed observations on peasant life a customs are shrewd and human He writes as a peasa and the translator has skilfully preserved the rustic tw of his language The book brings a breath of count air with it, reminding the town-dweller that agricultu is still the basis of life, and is a valuable, if inform contribution to sociology

ACCOUNTS of influenza in England in 1936–37 (Stuart-rris Andrewes and Smith 1938) and in 1939 (Stuart-rris, Smith and Andrewes 1940) have described the ncal features of the outbreaks of those years and the erimental studies then carried out on ferrets and mice. order to bring the story up to date and to help in imately viewing the epidemics of these times in per-ctive the following account of experiences in 1940 1 1941 is published

In 1940—Circumstances, in particular the absence oad of the clinical member of our team (C. H S -H), l not permit us to make correlated clinical and patho-ical studies in the spring of 1940 It may be said, wever that the outbreak of respiratory disease then valent in southern England was of the long-drawn- rather than sharply peaking form, that "clinically ical" influenza was relatively infrequent, and that a cheo-bronchitis with slow recovery was very prevalent rglings from patients diagnosed as clinical influenza re tested by intranasal inoculation of ferrets as in rlier studies The ferrets were observed for the velopment of fever or respiratory symptoms, and in any instances subsequently tested for immunity to fluenza A virus (Horsfall et al 1940) No evidence was tained that that virus was prevalent at all in southern gland in 1940 The garglings tested were of the llowing origins —

s already mentioned, none of these produced infection ferrets

In 1941—In spite of the absence of any general pidemic in the winter of 1940–41, sporadic cases of linical influenza occurred in London and elsewhere in outhern England We received during January and ebruary garglings or serum samples from 19 patients iagnosed as clinical influenza ; all but 2 came from the ondon area As will be shown, 8 of the specimens 42%) provided evidence that the disease was influenza A

During the same period, a detailed clinical study of he acute respiratory infections occurring in patients dmitted to a military hospital in southern England was eing made by one of us (C H. S -H) No actual pidemic was observed, but there was a sharply increased ncidence of cases in January and February, and many ases presented the clinical picture of influenza as seen n 1937 and 1939 Pathological investigations on 30 cases carried out locally and on material transported to Hampstead showed that 79% of the cases investigated in January and February were examples of virus A influenza As a number of cases of pneumonia and miscellaneous ailments were included, the actual incidence of virus A infection in cases of clinical influenza in the area was probably even higher A number of cases of influenza with the signs of bronchiolitis as seen in 1937 (Stuart-Harris et al 1938) were also seen, and each of the three cases investigated was found to have evidence of influenza virus A infection It is necessary to emphasise that the military hospital cases were selected only in so far as fever was concerned They therefore represented the average case of febrile acute respiratory infection during the period stated ; the investigations at the military hospital are described in more detail elsewhere (Stuart-Harris 1941).

The higher proportion of positive tests for influenza A virus infection in the group from the military hospital compared with those from London (79% : 42%) may be due to a real difference in the type of respiratory infection in the areas concerned It may, however, be only apparent, for the material examined from the hospital consisted for the most part of serum samples to be tested for antibodies , that from London comprised chiefly garglings for inoculation into ferrets As we shall show, the ferret test has proved, more especially this year, to be a far less delicate index of infection than the other.

Specimens from 16 patients from various districts were examined during March and April 1941 , not one gave evidence that influenza A was concerned

ATTEMPTS TO RECOVER VIRUS IN 1941

Tests on ferrets—Garglings from 22 patients were inoculated into ferrets between January and early March, 1941 The majority of the ferrets developed fever and symptoms of respiratory infection. Since it was not possible to make serial passages with all material believed to contain virus, some febrile ferrets were allowed to recover, then bled and their antibodies studied We confirmed earlier findings that no antibodies against the virus occurred in ferrets of our normal stock , accordingly the development of potent neutralising antibodies against influenza A virus in 3 inoculated ferrets was accepted as proof of the presence of A virus in the 3 specimens of garglings used to infect them. In 15 other ferrets fever or symptoms of nasal infection or both appeared, and serial passages were made at intervals of 3 or 4 days , 5 strains proved immunologically to be influenza A virus were thus established In previous years a strain once adapted to the ferret has been transmissible in series with great regularity , in 1941 less regular results were obtained, occasional ferrets in a series failing to respond with typical fever and symptoms Furthermore, 7 "strains" were obtained which were apparently capable of propagation for 2, 4, 5, 5, 6, 7 and 9 passages respectively, but eventually "petered out" and were lost Tests on sera from recovered ferrets in each of these series showed that no antibodies against influenza viruses A or B were present The symptoms of upper respiratory tract infection and the fever were, however, typical of influenza in the ferret, though there were rather more "misses" than with the 5 strains which proved to be A Cultures of turbinate suspensions were made as a routine , some trouble was met with by the picking up of *Pasteurella bronchiseptica*, hæmolytic streptococci and other organisms in the course of ferret to ferret passage, but ferrets receiving culturally-positive material have been excluded from the account just given On two occasions filtration through a gradocol membrane (average pore diameter 0 7μ) apparently permitted an active agent to pass

During these investigations those of us doing the ferret tests (C H A. and R E G) felt it likely that an agent, probably a virus, had been transmitted to and was being passed through ferrets , but that it could not be securely established in those animals No conclusive evidence of the correctness of this view was obtained Suspensions of ferret turbinates containing the supposed agent were passed serially through Swiss mice , with 3 strains passages were made through 5, 5 and 6 mice in series respectively , no virus was recovered. Inoculations of chick embryos amniotically (Burnet 1940a) were equally unsuccessful , filtrates of 6 strains of the series under discussion were used The queer results obtained in 1941 contrast sharply with those of 1940, when all the material inoculated into ferrets gave unequivocally negative results

Tests in chick embryos—As has just been mentioned, Burnet (1940a and b) has lately succeeded in infecting chick embryos by the amniotic route with filtrates of human garglings Infected embryos showed macroscopic changes in the lungs, or microscopic changes in smears of tracheal exudate , further, many embryos died After a few passages it was possible to adapt the strains to mice. Such by-passing of the ferret would represent a definite improvement in technique, since ferrets are not easy to work with in the average laboratory. Experience with two of our strains, TAY and BER, obtained early in January, 1941, seemed to confirm Burnet's findings, the changes described by him in tracheal smears of inoculated embryos were seen in one instance in the first chick embryos injected, and material from these chicks infected mice. Unfortunately, the first successes were the only ones, no other virus was induced to infect eggs straight from human garglings, though 21 were tested, 8 of them being certainly from cases of influenza A. In almost every instance at least 3 serial passes were made through chick embryos before the material was abandoned as negative. The loss of virus was confirmed by the negative results of complement-fixation tests (4 strains) or of ferret inoculations (3 strains).

---

* Member of the Health Commission to Europe International Health Division of the Rockefeller Foundation.

Infection of chick embryos was also attempted with strains which had previously been established in ferrets or mice. Ferret material of the BIR strain produced macroscopic changes in chick embryos at the third passage, and, after one further pass, infected mice, as will be seen later, we failed in two attempts with this strain to infect mice directly from ferret material. In other trials, made in the spring of 1941, filtrates of turbinate suspensions from 4 ferrets infected with the HER, WOR and WES strains of virus gave entirely negative results in chicks, though one (WOR) would infect the chick after previous adaptation to the mouse—a curious contrast to the findings with the BIR virus, which would go from ferret to chick but not directly from ferret to mouse.

Repetition of these attempts in June and July gave rather different results, ferret material of strains HER, WOR and WES was in each case successfully adapted to chicks after a few passes, and thence (HER and WES strains) to the mouse. The ferret material had been kept dried during most of the intervening time, and had only undergone one or two further passages in the ferret. It is probable that greater susceptibility of chick embryos in the summer accounted for the greater success, seasonal differences in the susceptibility of chick embryos have been recorded for ectromelia virus infection by Burnet and Lush (1936).

In positive embryos it was found, as also with well established strains like PR8, that, at any rate in later passages, an almost constant feature was depletion of the amniotic fluid around the embryo, so that embryos appeared "tied up in knots," often with their feet behind their necks and the membranes closely pressed around them. This finding has been in our experience more constant than anything in lungs or tracheal smears, indeed the changes described by Burnet have been noted only in embryos with the above described naked eye appearances. Altogether, the chick embryo studies have been disappointing, it remains to be seen whether the differences between our findings and Burnet's are due to differences between virus strains or between the eggs or some other, unsuspected, factor.

Work with mice.—In view of our failures in the past, we made no attempts to transmit a virus directly from man to mice. We tried to infect mice with the 5 strains established in ferrets. One (WOR) produced lesions after 4 passes through Swiss mice, this was found immunologically to be closely related to both the GAT and CHR strains of 1937 (Smith and Andrewes 1938). Three others failed to infect Swiss mice after 5 passages in series (MAR strain), 9 passages (WES strain), 5 and 9 passages in two separate trials (HER strain) and 7 passages (BIR strain). The WES and BIR strains were, however, later adapted to mice after being previously grown in chick embryos, as has already been described. It then appeared that the BIR strain was antigenically very like the TAL and CHR strains.

Two other strains (TAY and BER) infected mice after only one and two chick embryo passages respectively, these were serologically related to our 1937 CHR and TAL viruses. Since 1935, when several viruses were readily induced to pass from the ferret to the mouse, we seem to have encountered progressively greater difficulty in infecting mice with influenza viruses. In 1937 we succeeded with 8 out of 10 strains, obtaining lesions by the 5th or 6th passage, often earlier. In 1939 the results were not very different, and we seemed to be getting over the difficulties in adaptation by using Swiss instead of our own "farm" mice. In 1941 we have failed to adapt a number of strains directly from ferret to mice even when we used Swiss mice.

SEROLOGICAL STUDIES ON HUMAN SERA

Tests against influenza A virus.—As in previous years we have compared the neutralising antibodies in "acute" and convalescent sera, and have taken a five fold or greater rise in neutralising antibodies against influenza A virus during an illness as evidence of infection with that virus. Table I shows that of 34 pairs of sera from the military hospital taken in January and February the tests on 27 indicated that the patient had suffered from influenza A infection, 7 that the patient's infection was something else, 4 pairs of sera obtained in March and April disclosed no evidence that influenza A was concerned. Only small numbers of sera from other areas were examined (see table II).

TABLE I—RESULT OF TESTS ON MATERIAL FROM MILITARY HOSPITAL, JANUARY AND FEBRUARY, 1941

—	Virus A recovered in ferret test	No virus recovered in ferret test	No test in ferret
"A" infection indicated by serological test	1	2	24
Not an "A" infection by serological test	0	0	7

TABLE II—RESULT OF TESTS ON MATERIAL CHIEFLY FROM LONDON AND NEIGHBOURHOOD, JANUARY AND FEBRUARY, 1941

—	Virus A recovered in ferret test	No virus recovered in ferret test
"A" infection indicated by serological test	2	3*
Not an "A" infection by serological test	1*	1*
No serological test	5	7

* The serological diagnosis was here based on the antibody level in a "convalescent" bleeding only, no "acute" sample being available, the result is thus less dependable than when two specimens could be tested.

Tests against influenza B virus.—Since Francis (1940) described an influenza virus, named B, serologically unrelated to A, we have sought for evidence of its occurrence in England. None of the ferret inoculations carried out in 1941 yielded B virus. Of 8 sera from recovered ferrets, 3 were infected with A and 5 with something other than A, these were tested for antibodies against B virus, but none neutralised. Similarly 11 human sera from patients in Hampshire who failed to show a rise in antibodies against A virus in the course of their illness also gave no indication of infection with influenza B, though a low level of anti-B antibodies was present in all samples. There is thus no evidence that influenza B was prevalent in this country during 1941.

The presence of some antibodies against influenza B virus in human sera is possibly related to the existence of that infection in England in the past. Evidence will be published that some B was present in southern England in 1939.

DISCUSSION

Results shown in tables I and II confirm our previous experience that test of acute and convalescent sera for neutralising antibodies is a far more delicate index of infection than ferret inoculation, 5 patients whose garglings failed to yield virus yet seem to have been examples of influenza A as judged by the serological test. In spite of Burnet's promising findings, the amniotic method of chick inoculation has in our hands given even poorer results than has ferret inoculation.

In 1940 (Stuart-Harris, Smith and Andrewes) it was pointed out that a four-year cycle of major influenza epidemic peaks had been recently prevalent in England. Peaks in 1929, 1933 and 1937 had been interspersed with minor prevalences in 1931, 1935 and 1939 and almost nothing in the years adjacent to the peak years. If the cycle had continued, 1940 should have been a year free from influenza A—and so our laboratory studies indicated, but 1941 should have been a peak year, and this, fortunately, it did not prove, the deaths from influenzal pneumonia in London and the great towns having remained at a fairly low level.

One naturally wonders why no epidemic arrived, why the 1941 virus was so poorly adaptable to the ferret or from the ferret to the mouse, and why we could not reproduce Burnet's results in chick embryos, further, whether these facts are related The power of a parasite to produce disease—its virulence—is known to vary independently of its infectivity or power to spread from host to host It seems, however, that the influenza A viruses prevalent in England in the spring of 1941 were poor things in all respects , their infectivity for man was low, virulence for man not very high and virulence for laboratory animals also low

SUMMARY

No evidence of the presence of influenza A virus was obtained in material from the respiratory infections prevalent in England in the early months of 1940

In January and February, 1941 no widespread influenza epidemic occurred in England, but laboratory studies indicated that a considerable proportion of the sporadic clinical influenza prevalent in those months was due to influenza A virus The viruses recovered infected ferrets less easily than those of other years and were less readily adapted to infect mice In contrast to Burnet's recently published findings (1940), we only succeeded in 2 instances out of 23 in infecting chick embryos by the amniotic route directly from material of human origin

We wish to thank the medical men, both Service and civilian, who kindly provided us with material

EXTRA-ORAL SPLINTING OF THE EDENTULOUS MANDIBLE*

LEANDER POHL, M D VIENNA, L D S

IN treating fractures of the edentulous lower jaw or cases where resection of the edentulous mandible has to be performed, difficulties may arise so that fixation cannot be achieved by the methods commonly used, such as intra-oral splinting, splints in combination with flanges, saddles, hooks, screws, clamps, nails, circumferential wiring, bandages and so on Rhodes (1934), referring to fractures of the molar region when no teeth are present posterior to the fracture, writes " It is difficult to see how any dental appliance can overcome such a difficulty as this, even if treatment can be taken in hand at once " Kelsey Fry (1939), in a lecture on first-aid treatment of fractures of the jaws, says " I shall be surprised, however, if, by the end of the war, a satisfactory method has been found of replacing a displaced edentulous posterior fragment " Gillies (1935) doubts whether any surgical or dental control of the moderate displacement that occurs is either justifiable or possible in cases where the posterior fragment is short and edentulous Warwick James (1940) goes so far as to accept malposition in certain cases of extreme difficulty

One of the methods commonly used in the last war was to control the posterior fragment by vulcanite plates with flanges or saddles fitted to them Round (1939) describes a method similar in principle He fits a small bite block on a local cap of hard vulcanite fitting one or two upper teeth and carrying a cushion of soft vulcanite (Ash's soft rubber) to engage the lower fragment When the bite block is in position he wires the upper and lower teeth together, thus assisting the posterior fragment to take up its normal position

Nakamura (1937) has designed a device for splinting the edentulous posterior fragment by means of a metal screw vulcanised to a plate The screw fits into a channel drilled in the edentulous fragment, or is fixed by a wire ligature through a hole drilled in it He quotes a number of cases in which it was possible to leave the plate and screw in position from the date of resection until the final healing of the bone graft without complications

Bruhn and Lindemann (quoted by Wassmund (1927)) have treated a series of fractures by using the Codivilla-Steinmann nail traction The posterior fragment is drilled with a burr, and two silver or aluminium wires connected by a plate are passed through Schroeder's method (also quoted by Wassmund) is somewhat similar , he uses a metal plate which is fixed by means of a screw passing through a slit in it Foramitti (1917) fixes the edentulous fragment with a nickel splint screwed direct to the bone

Wassmund (1927) described cases which he treated by traction by means of an U-shaped wire passed through the bone and soft tissues Collins (1937) reports on a similar method, advocated by Ivy and Curtis (1931) After an incision at the angle of the jaw, a wire is passed through the bone, and its end is brought out through the skin and twisted into a loop The wire loop is attached to the wire in the head piece, which is incorporated in a plaster bandage around the head The two fragments are brought in perfect alignment after sufficient traction has been applied, and a firm union is achieved

Darcissac (1933) and Lenormant and Darcissac (1927) point out that fracture of the edentulous mandible is perhaps the only condition in which interosseous wiring is justifiable Their method is as follows (Darcissac 1933) An incision is made along the lower border of the jaw about 2 cm long The bone is drilled on each side of the site of the fracture with a burr 2–3 mm from the lower border A thick silver or bronze wire is passed through the hole and the ends twisted to form a loop by which traction can be made on the fragment The external wound is then closed The same procedure is done on the side opposite to the fracture so as to exert counter-extension on the larger fragment Traction is made by elastic to the two handles of wire passing round the neck Gillies (1935) advocates this method when the edentulous fragment is long and displaced and its control is of great importance He recommends for such cases either drilling a hole in the angle of the jaw and passing a wire retractor band through it, vulcanite appliances, or gutter splints, which can be fixed by circumferential wiring in order to obtain good alignment of the fragment without causing necrosis of the medullary portion of the bone Circumferential wiring is according to him particularly applicable to the depressed central fragment in an edentulous or partially edentulous case

Berry (1941) describes a method of fixation for fractures of the edentulous mandible in which vitallium screws are inserted vertically into the bone fragments through the oral mucous membrane The heads of the screws are then joined by a bar bent into appropriate shape The apparatus may be applied outside the mouth if desired

Rogers, Hall and Shackelford (1932) employ in certain cases open reduction intra-orally An incision is made, the two ends of the jaw are exposed and two holes are drilled in the bone, through which silver wire is passed and twisted together

The results of the various methods so far mentioned are not invariably satisfactory The value of flanges or saddles in combination with vulcanite plates of fixed metal splints is according to my own and others' experience (Wassmund 1927, Steadmann 1939, Fell 1940) questionable, for they invariably carry the danger of necrosis owing to abrasion and ulceration of the tissues overlying the posterior fragment, and offer but small hope of success My experience has been the same with wiring the fragment to a vulcanite plate Methods of drilling holes in the bone and passing nails screws or even wires through it as well, especially where a deliberate communication is made between the medullary portion of the bone and the oral cavity are open to the grave risk of causing necrosis Samuels (1934) reports a rare case of a fracture of an edentulous mandible where the patient died from embolism after holes had been drilled in the bone and wires passed through them Conditions are sometimes most unfavourable for bone-grafting Some of these methods are applicable only if enough teeth are standing in the larger fragment to provide anchorage for a plate Surgical intervention may sometimes not be possible owing to lack of accommodation, time or skilled personnel if a great number of cases have to be dealt with, for instance at a first-aid post behind the front line

The external splint suggested by Vaughan Tomey (1940) cannot be considered as a treatment splint but is a useful means of giving external support to a bandage and should prove useful in emergencies

According to my experience with the elevation of a depressed malar bone, Bruhn's hook-extension, a modification of nail-traction, seems to be far superior to other methods, for the hook being inserted only superficially into the bone, there are fewer cases of necrosis The method which I am going to describe is based on the same principle, using hook-extension (hook-traction) but avoiding most of the disadvantages of other methods Its principle is the extra-oral application of hook-screws into each fragment of the fractured mandible, and connecting them by a bar welded to them

---

* It was intended to read a paper on this subject at the Congress of Structive (Plastic) Surgery in London in 1937

DETAILS OF METHOD

The hook-screw (fig 1) is made of stainless steel in three sizes It consists of three main parts (1) a hook ending in a sharp point, the shaft of which is square in cross-section, (2) a simple screw tapered at one end and with a square head at the other, and (3) a connecting rod between the two The connecting rod is threaded at one end for the screw, and has a square hole at the other for the hook, as well as a locking screw

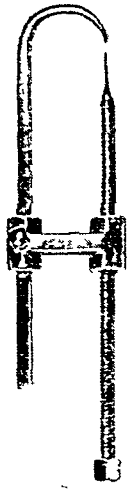

FIG 1—The hook screw

Insertion of the hook-screw —The site of insertion of the hook-screws depends on the type of fracture, the extent of external injuries present, and so on It is applied best at the thickest part of the bone and as far from the line of fracture as is considered necessary Before application the hook-screw is taken to pieces, and after the skin is surgically cleansed the hook is inserted so that injuries to vulnerable organs are avoided as far as possible As soon as one can feel bone either slight pressure or traction is exerted While the fragment is thus held in position with one hand by means of the hook the connecting rod together with the screw is slipped over the hook and then screwed tight The screw is then screwed down, and advanced into the compact bone only, in order to avoid any injury to the bone-marrow Three or four hook-screws should provide sufficient stability, but more may be used if necessary There is no difficulty in inserting the hook-screws in the body of the mandible or the horizontal ramus, whereas care has to be taken if the ascending ramus is very short in order to avoid damage to the facial nerve or the parotid gland (see case-record)

The bar —With the screws in position on both sides of the fracture a stainless steel bar 4 mm thick is bent to shape according to the position of the hook-screws and the extent of external injuries present The distance of the bar from the skin should be not less than an inch

The welding process —The hook-screws are then joined by means of the bar, which is welded to them in situ with the Rakos welder † (fig 2) after alignment of the fragments No special preparations are necessary except covering the skin with wet gauze for the heat during the welding process is only local A cold-water spray is sufficient to cool the metal, so that no ill effects to the adjacent tissues need be feared if ordinary care is taken

Welding has many advantages over soldering the bar on the screws previous to the insertion of the whole splint First, one never knows the exact position of the hook-screw before it is inserted Secondly, it may prove necessary to change one or the other hook before the fracture has united By the use of welding this can be done without removing the whole splint, thus avoiding undue damage to the bone Furthermore, any additional appliance can be welded to the bar—e g, in cases where absolute fixation may become necessary An additional bar is then welded to the main bar on one side, and fixed on the other to a head harness Other auxiliary appliances, such as extra-oral joints, can be fitted in the same way without removing the splint

FIG 2—Rakos welder in use

Nevertheless, although welding is in our experience preferable, the bar can be joined to the hook-screws by means of special screws, or even soldered

CASE-RECORD

Exact anatomical studies had been made regarding the site and mode of insertion of the splint as well as experiments with materials and the welding process before the technique was applied to the following case.

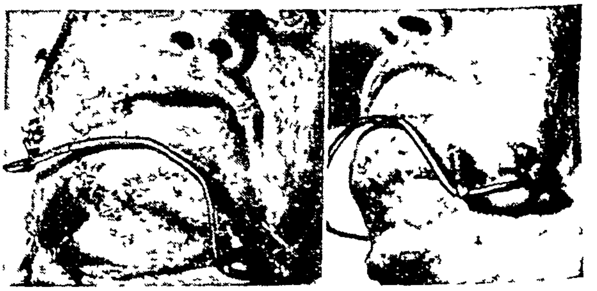

FIG 3—Hook screw splint in position, immediately after operation

A man, aged 57, complained of pain and swelling in the right horizontal ramus of his mandible His mouth was practically edentulous, for the lower canines, the only teeth present, were both very loose A swelling could be seen extending from the right lower canine to the angle of the mandible, covered by normal mucosa It was painless to palpation and showed the typical signs of a cyst The radiogram seemed to confirm the diagnosis, but one very small hard indolent gland in the right submaxillary region caused suspicion of malignancy After the cyst had been dissected out in the usual way microscopical examination of the cyst wall confirmed the suspicion of carcinoma

Previous to the radical operation both canines were removed and dentures fitted After a block dissection ‡ of the affected glands and the soft submaxillary tissues involved, the diseased portion of the mandible was freed from its mucosa and

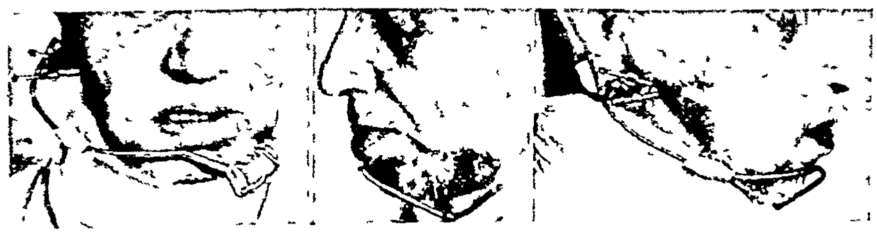

FIG 5—Three weeks after operation

---

† The Rakos process is a fusion welding It is executed with a high resistance welding torch which is brought into direct contact with the pieces to be welded, thus preventing the development of a stationary arc The temperature employed is about 3000° C This heat is developed within a fraction of a second, and the welding completed before the heat can be conducted from the welding spot Thus, in spite of the intense concentration of heat there are no ill effects to tissues or materials in the immediate vicinity of the spot welded, even within the patient's mouth The electric power used is of very low voltage, thus avoiding any danger of electric shock The apparatus is now manufactured in England by Technotherm, Ltd, of 113, Victoria Street, St Albans

‡ The operation (resection of the mandible and bone grafting) was performed in collaboration with Dr O Hofer at the Policlinic in Vienna in June, 1937

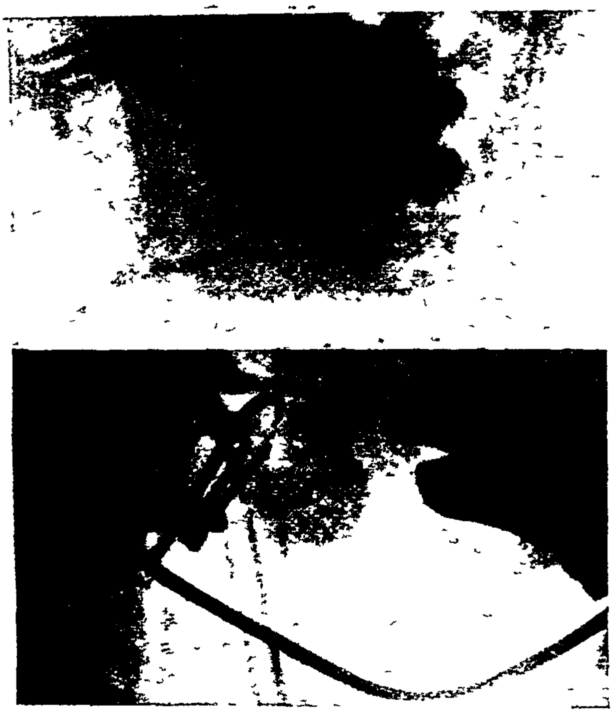

FIG 4—Radiograms showing hook-screw splint in position Above, anteroposterior view, below, lateral view of posterior fragment.

periosteum The splint was then applied as described above before the bone was severed Two of the hook-screws were inserted in the ascending ramus and two others before and behind the left mental foramen Fig 3 shows the patient immediately after the resection of his mandible with the hook screw splint in situ In fig 4 the positions of the hook screws are seen in radiograms The posterior fragment was kept in position, and the patient was able to move his temporomandibular joints and chew gently shortly after the operation The skin around the hook screws was painted with Mastisol and covered with silver foil immediately after their insertion to reduce the danger of external infection No signs of necrosis could be observed during the whole course of treatment, the only complication being a salivary fistula which developed at the site of one hook screw on the ascending ramus This unpleasant incident was of course, anticipated, and is unavoidable with other methods as well if the posterior fragment is short Fig 5 shows the patient three weeks after the operation The salivary fistula healed without any surgical intervention when the splint was removed after six weeks, leaving only slight scars at the site of the hook screw The posterior fragment remained in correct position until bone grafting was performed

DISCUSSION

The method described has been applied in this single case only, for circumstances did not allow me to make further investigations on this subject But it proved so successful that I should like to see it more extensively used It seems to offer an alternative way of treating cases where other methods are not satisfactory It permits immediate reduction and fixation of the fragments without losing valuable time in the preparation of splints The mouth, as well as all the parts of the face are left free for any surgical treatment which may be necessary in a case of major injuries Any alteration in construction required during the course of treatment is easily made without changing the splint or interrupting fixation Proper feeding is facilitated from the first day after the splint has been inserted, and the patient is even enabled to masticate to a certain degree—both important advantages of this method The mouth can be kept clean, and the muscles show much less atrophy because partial function is maintained The simplicity of the technique allows its use by those without any special knowledge of dentistry Its use should be limited to suitable cases [No doubt the posterior fragment is best left alone when displacement is only moderate and the fragment very short But the method might prove useful in cases with much displacement as well as those with great loss of substance, especially of the body of the mandible, in order to avoid unsightly disfigurement and allows unrestricted movement of the temporomandibular joint

SUMMARY

A method is described for the fixation of fractures of the edentulous mandible by means of steel hook-screws attached to each fragment and connected together by a bar welded to them in situ

The technique is especially suitable for fractures in the region of the angle, or where there is great loss of substance in the body of the mandible It permits immediate reduction and fixation without loss of time in preparing splints The mouth and face are left free for necessary surgical treatment Feeding is facilitated and the patient can chew to a certain extent as soon as the apparatus has been applied The mouth can be kept clean and the muscles of the jaw can be exercised sufficiently to prevent atrophy

EXTERNAL PIN FIXATION FOR FRACTURES OF THE MANDIBLE

RAINSFORD MOWLEM,
M B N Z, F R C S

J L DUDLEY BUXTON,
L M S S A, L D S

ALEXANDER B MACGREGOR,
M B CAMB, L D S
SQUADRON-LEADER R A F V R

JOHN N BARRON,
M B N Z, F R C S E

From the Maxillo-facial Unit, Hill End E M S Hospital

FRACTURES of the mandible in the tooth-bearing area present a problem which can be efficiently solved by purely dental methods The Curtis loop, the arch wire or the dental cap splint offer a good chance of an excellent result When the patient has no teeth or when the fracture occurs behind the tooth-bearing area, the problem is not so simple In the region of the horizontal ramus Gunning splintage with circumferential mandibular wires is likely to succeed, but in fractures through or posterior to the angle the accepted methods of fixation have not proved universally satisfactory These methods have included ingenious intraoral splints with extension apparatus intended to bear on and control the ascending ramus Such methods depend for their success on the capacity of the mucous membrane to withstand pressure, and this capacity is limited to that part of the jaw which normally carries teeth The alternative has been to fix the anterior fragment in correct relation to the upper jaw, and to apply traction to the angle of the mandible by means of a wire loop passed through the bone and then fixed either to a post-auricular support or by means of a bar to the cap splints on the anterior fragment A wire at the angle, however attached, controls flexion at the temporo-mandibular joint but cannot and does not control the other two deformities —rotation and adduction

We therefore considered that the method of crossed Kirschner wires, as introduced by Roger Anderson for

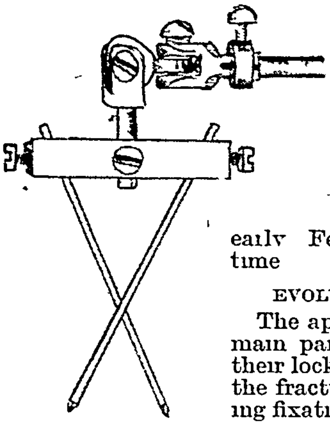

FIG 1—Earliest type of plate and bar

long bones might enable us to apply direct skeletal fixation to the mandible It may be of interest to follow the evolution of the method of applying these pins and of the type of intervening fixation from our first case in early February to the present time

EVOLUTION OF APPARATUS

The apparatus consists of three main parts a pair of pins and their locking plate on each side of the fracture line, and an intervening fixation bar

Standard Kirschner wire is used, and it has been found that sizes smaller than 1 5 mm in diameter are insufficiently stable, particularly under torsion The wires, therefore, consist of 2 or 2½ in lengths of 1 5 mm Kirschner steel sharpened to a short bevelled pyramidal point A pair of wires, crossing each other at an angle of about 60° before entering the bone, are introduced on each side of the fracture line and about ½ in away from it They are inserted close to the lower margin of the bone to avoid the inferior dental canal and they penetrate as far as the inner plate It is now necessary to lock the outstanding ends of each pair together The earliest type of plate used for this purpose is shown in fig 1 It was found to be awkward in use, and a split type was then introduced The screw employed to clamp the two halves of each plate together was at first also used to fix the connecting bar which ultimately unites the plates This meant that each time an adjustment was made the plates had to be loosened on the pins and control of the bone fragments from outside was lost In the next type (fig 2*a*) the two halves of each plate were clamped together by two separate screws and a third screw was used to attach them to the connecting bar This was too cumbersome, and fig 2*b* shows a later type in which only a single thickness of metal is required

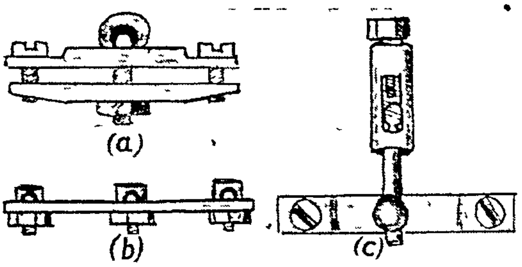

FIG 2—*a* and *b*, stages in development of plate, *c*, universal joint at end of bar

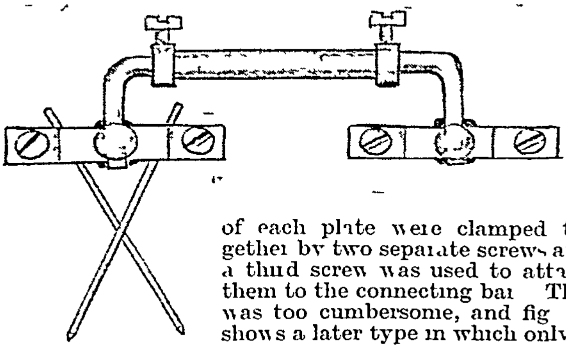

FIG 3—Last stage but one in development of apparatus

The next problem was to devise an intervening bar This must be capable of lying slack and allowing movement in any direction so that the fracture can be easily reduced When reduction is effected the bar must be capable of being locked rigidly in its final position The first type of bar contained, in effect, two universal joints, one of which is shown in fig 1 It worked well, but was felt that if these joints were to be of reasonable the chances of positive fixation were small We therefr tried to use a single piece of ⅛ in German silver wa which was to be bent to the required shape on the op ing table, but it was found that minor corrections difficult to make, even with specially devised keys T third type incorporated a universal joint at each end the rigid bar (fig 2*c*), but no miniature universal is really satisfactory The next type of fixation (fig consisted of two ⅛ in rods, bent at right angles and fitte into a short length of tubing These rods were attache to the plates in such a way that universal movement wa possible At the same time positive locking was ob by only four screws one on each plate and two on th central tube The whole apparatus is extremely simp and can be constructed by any mechanic, even withou specialised tools An even simpler type is now used, which one of the screws on the tube has been eliminate On one or two occasions pins have become slack betw the second and third week, and the weight of the appara tus may have been partially responsible for this have therefore constructed the appliance in alloy and it now weighs considerably less than half ounce Its construction and use are shown in fig 4

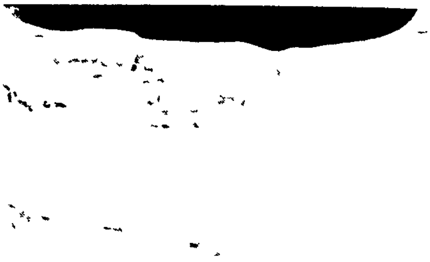

FIG 4—Latest type of apparatus applied to skeleton jaw

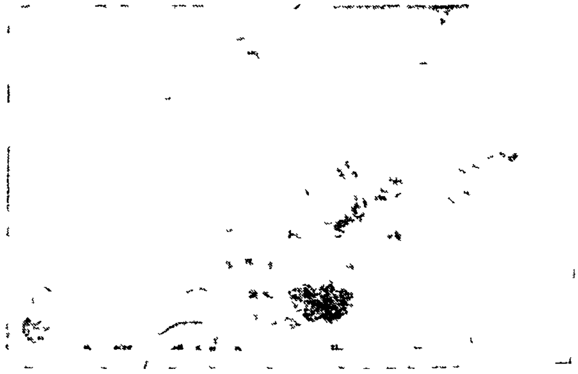

FIG 5—Radiogram of early type of splint in use

FIG 6—Patient opening his mouth 18 hours after fixation of fracture

It may be argued that the introduction of 1 5 mm Kirschner wire through the skin of the face is an unwarranted barbarism Against this must be offset three facts First, hardly any discomfort is experienced by the patient Secondly, fixation is so positive as to enable the surgeon to avoid locking the mandible to the upper jaw in many cases ; the resultant maintenance of movement of the temporomandibular joint ensures that blood-supply remains at its optimum, the patient is enabled to eat in comfort and oral cleanliness is readily obtained Thirdly, such scars as do occur seldom need treatment but at the worst it is simple to carry out the necessary minor excision under a local anæsthetic

The apparatus has now been used in 19 cases We feel that the principle is worthy of further elaboration though it is probable that it will be applicable only to chosen cases and that it should not be used to replace the simpler and more standard methods for the great majority of fractures

SUMMARY

By the use of an orthopædic principle it has been possible to elaborate an apparatus to control fractures of the mandible occurring behind the tooth-bearing area

A pair of crossed Kirschner wires are inserted into each fragment Various methods of locking each pair into a unit and then joining the units to maintain reduction are described

The advantage is absolute fixation by extra-oral means Oral cleanliness is readily obtained and function at the temporo-mandibular joint is maintained Postoperative discomfort is negligible and feeding is simplified The disadvantage is the occasional necessity to treat the small residual scars

The method is in the early stages of its elaboration and its use should be limited to those fractures which cannot be adequately controlled by standard methods

BLOOD CHANGES FOLLOWING CONTROLLED HÆMORRHAGE IN MAN

JOHN WALLACE *
B SC , M.B EDIN

E P SHARPEY-SCHAFER,
M.R C P

With technical assistance of A C PINCOCK

(From the Department of Medicine British Postgraduate Medical School)

RECENT experience of the treatment of air-raid casualties in the resuscitation wards has shown that most of the cases requiring intravenous infusions are suffering mainly from the effects of hæmorrhage On admission of a patient to hospital it is often difficult to assess the amount of bleeding which has taken place It is not until a day or two later, when the degree of maximum dilution can be measured and when blood corpuscles have not been transfused in treatment, that the extent of the hæmorrhage can be estimated The clinical picture of such a patient may be complicated by wound infection or other conditions which reduce hæmoglobin percentage, but in the majority of cases reduction of hæmoglobin indicates hæmodilution following hæmorrhage A simple method of measuring circulating blood-volume would be of great value although there is still the objection that the original blood-volume is unknown Such a method is not at present available

The hæmoglobin percentage in a case of recent traumatic hæmorrhage gives no indication of the extent of the hæmorrhage, since dilution may not have occurred The object of this work has been to investigate the course of dilution following controlled hæmorrhage Hæmoglobin percentages, plasma proteins blood-pressure and pulse changes have been followed, as well as blood-volume, plasma-chloride and blood-urea in a few cases

METHODS

Volunteers were venesected and 28 observations were made The subjects were convalescent hospital patients and each one had a thorough clinical examination were found to have normal circulatory systems : from three cases (Nos 6 7 and 9) who had hyperten The clinical diagnoses of those with normal circul: systems were neuroses (nine cases) chronic ne diseases (eight cases) chronic bronchitis (two c: convalescent lobar pneumonia (two cases), uncompli gastric ulcer, orthostatic albuminuria undesce testicles and headache (each one case) Two sub (Nos, 2 and 7) were found to have low initial h: globin ; both had been previously bled and regener of hæmoglobin was not complete Nos 7 and 9 13 and 24 are the same subjects venesected on diff occasions

Venesection was performed in the usual m: through a wide-bore needle, the subject resting couch with the trunk at an angle of 30° Care was t to keep the subject warm and at a constant temper: An initial resting period was allowed for blood-pre: pulse and hæmoglobin estimations to reach an librium

Hæmoglobin was estimated by taking 0 02 ml samples from a freely flowing ear puncture and estim the percentage by a photoelectric method (Hill and Pi to be published) accurate to 0 4% (standard error)

Plasma-proteins, plasma-chlorides and blood-urea estimated by the methods of King, Haslewood and I (1937)

Blood volumes were estimated in three subjects modified carbon monoxide method This was in pri similar to that described by Hartmann (1937) excep the use of red and infrared light instead of green and light for measuring carboxyhæmoglobin

RESULTS

The main data are shown in the table

Blood-pressure —Sixteen subjects showed a fa blood-pressure, but in eight of these the pressure returned to its previous level within an hour , cases (Nos 12 26 and 28) showing this temp reduction in blood-pressure developed a simulta: bradycardia of 60 beats per minute or less , in subjects the fall in blood-pressure was prolonged as much as 24 hours, a group which included two h tensive subjects

The fall in pressure usually occurred with dra: suddenness at the end of venesection which was st at the first sign of a fall Other symptoms appea the same time The face became pale the skin and clammy, and the respiratory rate frequ increased Yawning was also a prominent fe: The patient complained of faintness dizziness nausea There was frequently a desire to def: and urinate, and one subject actually passed Unconsciousness often supervened, with depressi respiration cyanosis twitching of the limbs rot of the eyes, disappearance of the heart sounds absence of pulsation in the large arteries Brady occurred with the first fall in blood-pressure and sisted Loss of consciousness was usually brief case 6 was unconscious for five minutes Case 2: a fall of blood-pressure, bradycardia and syncope the removal of 500 c cm blood , he was then al to recover, and half an hour later a further 600 was withdrawn without a significant change in pressure or a recurrence of other symptoms

In nine subjects the effect of posture on sy blood-pressure and pulse was investigated after section All showed a striking and immediate f systolic blood-pressure on sitting sharply upright couch The extent of this fall was in every case g than 40 mm Hg and always occurred within 10 se of sitting upright If the sitting position was maint: in most cases the systolic blood-pressure rose 30 seconds to its previous resting level or to a slightly lower than that resting level but in a few syncope terminated the observation Fig 1 illus this exaggerated response of systolic blood-press alteration in posture compared with the normal re: in the same individual after he had restored his o blood-volume The heart-rate, which was follow continuous electrocardiographic tracings show tachycardia with an increase of more than 30

PR + = Exaggerated response of blood pressure to postural changes Vs = venesection Max = maximum

per minute, except in two cases where a bradycardia developed On lying back there was in every case a rapid return of the blood-pressure and heart-rate to normal The nine subjects who showed this response are indicated in the table by PR + This exaggerated response to posture could be repeated at will, and some subjects still showed the response 5 or 6 hours after venesection

Pulse-rate —Six subjects (Nos 1, 5, 6, 12, 26, 28) showed bradycardia, always associated with a fall of blood-pressure, another five (Nos 2, 3, 8, 9, 15) showed tachycardia with a rise of heart-rate of more than 20 beats a minute, the remainder had little or no change in heart-rate

Hæmoglobin percentage and blood-volume —Initial dilution as judged by the hæmoglobin values was small Eight subjects (Nos 1, 3, 5, 6, 8, 19, 26, 28) showed a fall of Hb of 5% or more and the rest less than 5% The majority of the cases showed a maximum dilution which corresponded closely with the theoretical dilution calculated on the assumption that the blood-volume was five litres Three subjects (Nos 6, 21, 22), however, showed a maximum dilution which was considerably greater than the calculated figure, and in two of these subjects actual blood-volume estimations confirmed that there had been an overdilution and that the blood volume had increased over the initial value In cases 19, 21 and 22 the theoretical dilution is calculated from the observed blood-volume Case 13 seemed to show failure to dilute to the theoretical figure, though followed for a considerable period A week later the same subject (24) was again venesected, and on this occasion showed a normal dilution The time taken to reach a maximum dilution showed great variation, from 3 to 90 hours, no reason has yet been observed why some subjects take a long and others a short time to reach maximum dilution

Plasma-protein, plasma-chloride and blood-urea —There was but little change in plasma-proteins while dilution was taking place Cases 9 and 21 showed a fall, case 21 being one of those with over-dilution, while case 8, who had a rapid dilution, showed a rise in plasma proteins There was no significant change in plasma chlorides after venesection Blood-urea changes were also negligible except in cases 6, 7 and 9, who had hypertension with some renal involvement The duration of the azotæmia in case 9 is illustrated in fig 2

DISCUSSION

The mechanism of dilution and regeneration of plasma-proteins and hæmoglobin after experimental hæmorrhage in animals has been reviewed by Whipple (1938) In man, Stead (1940) removed 760–1220 c cm of blood from six subjects Five showed a sudden fall of blood-pressure and bradycardia There was an immediate small dilution with protein-poor fluid, and dilution continued up to 72 hours without further changes in plasma-proteins Our results show that the rate of dilution varies greatly in different subjects, and that therefore the hæmoglobin percentage estimated at an arbitrary time after hæmorrhage from an injury may give no indication of the extent of the hæmorrhage The rate of dilution may also vary in the same subject, as illustrated by cases 13 and 24, the same subject being venesected on two separate occasions at an interval of 5 weeks There was no obvious change in conditions between the two observations, and regeneration of blood had taken place

The dilution of hæmoglobin is not paralleled by a dilution in plasma-proteins In only one subject, case 21, was the small initial dilution associated with the passage of a protein-poor fluid from the tissues into the blood Further fall of hæmoglobin continued without dilution of plasma-proteins, suggesting that there are available proteins in the tissues which pass into the blood-stream and maintain its colloidal content The mechanism of this mobilisation of proteins is unknown, although there is evidence that the liver is an important source (Whipple 1938) and the cells of the reticulo-endothelial system may play a part (Cutting and Cutter 1935) Over-dilution may occur occasionally, a phenomenon that might be of clinical importance when considering the transfusion of patients with low hæmoglobin levels after hæmorrhage, and indicating the advantage of actual blood-volume estimations in such states

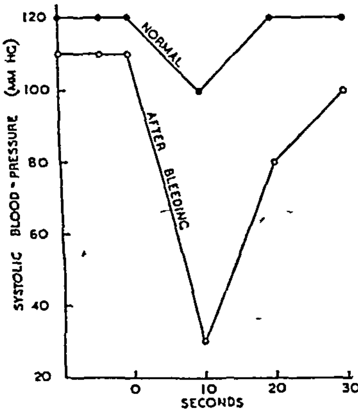

FIG 1—Exaggerated response to sitting up after bleeding

The fall of blood-pressure in certain subjects has a practical application to "shocked" casualties and the bleeding of donors Emotional causes seem unlikely in our subjects, since the fall occurred only at the end of a large venesection, and a sudden drop of blood-volume appears to be the initiating mechanism The prolonged fall in a few cases is in accord with well-known clinical observations after hæmorrhage The exaggerated postural response may be part of the same mechanism, for it is known to happen in other conditions in which there is reduced venous return, such as long standing in the erect posture (Turner 1927) and untreated Addison's disease (Berry, Horton and MacLean 1940) Although an exaggerated postural response can occur in conditions in which there is no reduction of blood-volume, yet its presence in casualties suffering from hæmorrhage may be one further indication that a diminished blood-volume is present Thus the postural response may be of value clinically to demonstrate reduction of blood-volume after suspected hæmorrhage The pulse-rate seems to be of little value after hæmorrhage, since it may be slow, fast or show no change, an observation that agrees with the findings in air-raid casualties that have bled extensively (unpublished data)

The insignificant alteration in plasma-chloride confirms the observations made by Black (1940) after experimental hæmorrhage in dogs The same worker observed a slight rise in blood-urea, but this is not confirmed except in those cases in which there is pre-existing renal damage

Mr D K Hill was responsible for the blood volume estimations, and coöperated in the study of some of the cases in this series Biochemical estimations were made in the school laboratories (director, Dr E J King)

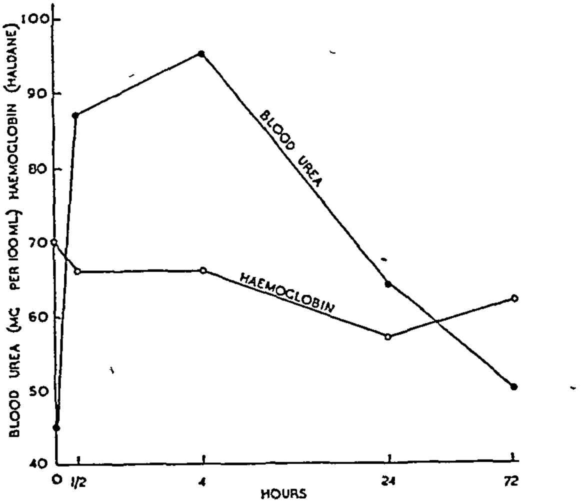

FIG 2—Azotæmia following bleeding in subject 9 with malignant hypertension Venesection of 1100 c cm was carried out at zero time

SUMMARY

Twenty-seven convalescent patients with normal circulatory systems were bled up to 1150 c cm and blood-pressure, pulse-rate, hæmoglobin percentage, plasma-protein, plasma-chloride, blood-urea, and, in a few subjects, blood-volume were followed

Sixteen showed a fall of blood-pressure with syncope, six of these had bradycardia In half, the fall of blood-pressure was temporary, in the rest it was prolonged up to 24 hours The response to posture (fall of blood-pressure on sitting up) was exaggerated in all of nine subjects investigated

The heart-rate may be slowed, increased or unchanged after hæmorrhage

The time taken to reach maximum hæmoglobin dilution varied greatly, from 3 to 90 hours average (32 hours) Three subjects showed overdilution

Plasma-protein concentration showed little or no change while dilution was taking place Plasma-chloride showed no change, nor did the blood-urea except in cases with known renal impairment

PHARMACY IN EXILE —The college of the Pharmaceutical Society continues to sojourn happily in Cardiff, while the pharmacological laboratories and the department of nutrition have found a billet with the National Institute for Research in Dairying at Reading As Mr H Berry, dean of the college, in the annual report for 1940, points out, reduction in teaching staff has decreased the amount of research work, but even so the report contains much that is of interest to the medical researcher in war-time The influence of cooking on the vitamin-content of food, the components of acriflavine and the chemistry of the vitamin-B complex are some of the subjects which have engaged the attention of the college staff The department of pharmacology records a rapid and convenient method for the assay of heparin, and observations on the property of a transparent artificial resin, perspex, to delay the clotting of blood, suggest that this substance may replace the paraffin-lined test-tubes and paraffin-lined glass cannulæ used in animal experiments

PR + = Exaggerated response of blood pressure to postural changes Vs = venesection Max = maximum

per minute, except in two cases where a bradycardia developed On lying back there was in every case a rapid return of the blood-pressure and heart-rate to normal The nine subjects who showed this response are indicated in the table by PR + This exaggerated response to posture could be repeated at will, and some subjects still showed the response 5 or 6 hours after venesection

Pulse-rate —Six subjects (Nos 1, 5, 6, 12, 26, 28) showed bradycardia, always associated with a fall of blood-pressure ; another five (Nos 2, 3, 8, 9, 15) showed tachycardia with a rise of heart-rate of more than 20 beats a minute , the remainder had little or no change in heart-rate

Hæmoglobin percentage and blood-volume —Initial dilution as judged by the hæmoglobin values was small Eight subjects (Nos 1, 3, 5, 6, 8, 19, 26, 28) showed a fall of Hb of 5% or more and the rest less than 5% The majority of the cases showed a maximum dilution which corresponded closely with the theoretical dilution calculated on the assumption that the blood-volume was five litres Three subjects (Nos 6, 21, 22), however, showed a maximum dilution which was considerably greater than the calculated figure, and in two of these subjects actual blood-volume estimations confirmed that there had been an overdilution and that the blood volume had increased over the initial value In cases 19, 21 and 22 the theoretical dilution is calculated from the observed blood-volume Case 13 seemed to show failure to dilute to the theoretical figure, though followed for a considerable period A week later the same subject (24) was again venesected, and on this occasion showed a normal dilution The time taken to reach a maximum dilution showed great variation, from 3 to 90 hours , no reason has yet been observed why some subjects take a long and others a short time to reach maximum dilution

Plasma-protein, plasma-chloride and blood-urea —There was but little change in plasma-proteins while dilution was taking place Cases 9 and 21 showed a fall, case 21 being one of those with over-dilution, while case 8, who had a rapid dilution, showed a rise in plasma proteins There was no significant change in plasma chlorides after venesection Blood-urea changes were also negligible except in cases 6, 7 and 9, who had hypertension with some renal involvement The duration of the azotæmia in case 9 is illustrated in fig 2

THE LANCET

LONDON: SATURDAY, OCTOBER 4, 1941

COLONIAL WELFARE BEGINS ITS CLIMB

Our colonial empire, as distinct from the dependencies and mandated territories administered by the dominions, is inhabited by 60 million people, two-thirds of whom live in Tropical Africa and the remainder mostly in the West Indies, Ceylon, Hong-Kong and Malaya. The colonies are administered by more than forty separate governments, and are responsible for an enormous volume of trade: in 1939 the value of exports amounted to more than £4 per head of population, the imports to £3 10s. About a quarter of the average expenditure is on social services; but since the revenues in many colonies are small in relation to their size, while the field of social service to be covered is very large, the sum is grossly inadequate. The Earl of Listowel, speaking in the House of Lords on July 9, showed how the principle of trusteeship on which the colonies are held and administered had been disregarded until 1929 when the first Colonial Development Act was passed. Even this was aimed more at relieving unemployment at home than at stimulating production of subsistence crops in the colonies. But last year, with the passing of the Colonial Welfare and Development Act, opportunities for raising the standard of living among the native populations have been greatly increased. This act authorises the expenditure of up to £5 million a year for ten years, with an additional yearly grant of half a million for research. Lord Moyne, speaking in the same debate, said that but for the war the expenditure authorised might have been much higher. Last year the fall of France made it necessary to convert every available penny into aeroplanes and arms; but this year it is felt that war or no war we must not let the peoples of the colonies—many of whom already live at too low a standard—suffer from the disorganising effects of war. The obligation is the greater because the colonies have been so generous in offering us help, amounting already to more than £20 million. Some have offered their surplus revenues as a gift for the prosecution of the war. Lord Moyne, uneasy about accepting these generous offers from the poorer colonies, has proposed that they should be accepted as loans, to be repaid in time to come, for post-war development. The effects of the war on the various colonies have been uneven; a few produce materials which are in demand, and they are in a state of unwonted prosperity, especially Malaya and Northern Rhodesia; in others, such as the West Indies, there has been no serious interruption of their usual economy; but a few—especially Malta and Cyprus—are cut off from their ordinary trade; and some have lost their overseas markets through lack of shipping space—West Africa, for example, cannot dispose of cocoa and palm products, East Africa of sisal, Palestine of oranges or Jamaica of bananas. The home government has helped in these difficulties by buying up crops or financing the growers in other ways.

At the outbreak of war there was for a time a tendency towards the arrest of social programmes, but now the aim is to carry on all that were in progress and to plan ahead for others. Much of the personnel, of course, has been seconded for military service, but recruitment has been officially approved and young doctors are advised that service in the colonial empire is of as much national importance as service in the forces. The Mediterranean colonies of Gibraltar, Malta, Cyprus and Palestine are in a peculiar position at present and their medical services are necessarily subordinated to war needs. In other colonies schemes initiated before the outbreak of war are still being maintained. In Sierra Leone, for example, a campaign against sleeping sickness and yaws had been newly begun when war broke out and this is being carried on, the cost of it being £50,000 for three years. In the gold fields an attempt to get rid of onchocerciasis by evacuating the area for a time was found to be holding up gold production seriously; Mr. J. J. C. Buckley, D.Sc., of the London School of Hygiene and Tropical Medicine has been seconded there and is making progress in the study of the simulium fly responsible for spreading the disease. In Nyasaland Dr. B. S. Platt, a member of the staff of the Medical Research Council, directed a team to make a nutritional survey, and this piece of work has been continued although on a diminished scale. The M.R.C. have also cooperated in other directions, and Dr. Frank Hawking and Dr. A. J. Haddow holding M.R.C. fellowships for research in tropical medicine worked in Tanganyika and in Kenya. Dr. E. M. Lourie, a member of the M.R.C. staff, has been carrying on research in chemotherapy in connexion with the sleeping-sickness survey in Sierra Leone which is being conducted by the local government with a grant from the Colonial Development Fund. Prof. D. B. Blacklock of the Liverpool School of Tropical Medicine, and Dr. Carmichael Wilson of the Colonial Medical Service, are carrying out an investigation at Freetown into the occurrence of malaria there. Dr. G. M. Findlay of the Wellcome Research Institute has recently made tours in East and West Africa and the Sudan to study the incidence of yellow fever, and has made reports and suggestions. He has emphasised the need for further research and coordination in the African territories. Much investigation has also been going on at Entebbe under Dr. A. F. Mahaffy of the Rockefeller Foundation, the unit there having been established for several years. Many public-health measures to be effective must be on a massive scale; for example, a sleeping-sickness campaign is going on in Nigeria, where a fly-free belt is being created some 70 miles long and 20 miles wide—the size (say) of Salop or Wilts. The first part of the work entails the destruction and clearance of jungle and undergrowth and is thus a considerable task. It represents one aspect of a settlement scheme, with the provision of safe water-supplies, of sanitary latrines, and of clean markets for meat and food. In Tanganyika a central development committee has been established and the study of trypanosomiasis and the tsetse fly is going on. In Northern Rhodesia a plan for establishing rural dispensaries is being continued; a new maternity block, the gift of the Beit trustees, and a pathology laboratory have been opened, and there is provision for more hospitals. In British Guiana the spread of malaria and yellow fever is being investigated, with

Antigen skin test strongly positive

Autopsy performed by Dr Arthur Davies showed the following positive findings Lungs Subpleural petechial hæmorrhages, with zones of hæmorrhage in substance of left lung, basal congestion and œdema Heart and liver extreme fatty degeneration

Stomach and uterus few petechial hæmorrhages

Right psoas muscle extensive hæmorrhage into substance (similar findings in a case of fatal trichiniasis were described by Frothingham in 1906)

Prof R T Leiper demonstrated microscopically the presence of a trichinella larva in the tendinous portion of the diaphragm

Histological examination (Dr A B Bratton) Microscopical examination shows presence of larvæ in voluntary muscle, numerous in tongue, scanty in diaphragm and right psoas muscle, in these sites also foci of inflammatory infiltration shown by serial sections to indicate proximity of a larva in many cases but not in all, such foci present in laryngeal muscles and an intercostal muscle, though sections include no larvæ Myocardium shows subacute inflammation, mainly focal, serial sections do not show larvæ, even in vicinity of inflammatory foci Excess of eosinophil leucocytes in sternal marrow Sections of lung, liver, spleen, kidney, suprarenal, pancreas, gall bladder, duodenum, uterus, thyroid, frontal, parietal, temporal and occipital cortex, centrum semi-ovale, basal ganglia, pons, medulla and cerebellum show neither larvæ nor inflammatory foci

COMMENT

The mental attitude of the patients was identical with that seen in encephalitis It is noteworthy that this is the most fatal form of trichiniasis "Splinter" hæmorrhages were present under the toenails in one case as well as under the fingernails in both As far as we know, hæmorrhages under the toenails have not so far been reported in this country Other notable features were the persistent splenomegaly in case 1, and the detection of the embryos in the blood in case 2, (probably the first time that has been done in this country)

We must thank Dr W Allen Daley, medical officer of health, L C C, for permission to publish this paper, and Dr B A Young, medical superintendent of St Alfege's Hospital, Prof R T Leiper, F R S, Dr Arthur Davies, Dr A B Bratton, Dr E N Allott and Dr E Davis for their cooperation

Reviews of Books

Surgery of Modern Warfare

Part V Editor Hamilton Bailey, F R C S, surgeon to the Royal Northern Hospital, London Edinburgh E and S Livingstone Pp 641-876 17*s* 6*d*

With this instalment the book is complete Wounds of the neck are discussed and the central nervous system is covered by experts in neurology and neurosurgery A section is devoted to diseases encountered in subtropical countries, another to the administration of casualties in the Navy, the Army and the E M S, and an appendix reviews recent articles on war surgery In the section on the care of the bladder in spinal injuries the author advises suprapubic cystotomy as a routine, a conclusion to which most surgeons of experience are coming In dealing with burns he shows a reluctance to abandon measures of proven value for such as have yet to stand the test of time The articles on organisation are excellent, but it is doubtful whether first-aid posts can act as filters, cases being taken there and sorted before being transferred to more fully equipped hospitals If a patient is ill enough to require an ambulance he should be taken direct to hospital, F A P 's dealing with ambulance cases only when they are isolated or when neighbouring hospitals have been put out of action Posts near or attached to big hospitals should deal only with walking wounded The writer on head injuries refers to cerebral compression by bleeding from intracranial veins, without explaining how this can happen with blood at a lower pressure than normal cerebrospinal fluid The editor reopens the question of tying the vein also when it has been necessary to tie the artery to a limb The book in fact fairly bristles with controversial matter A fine level of production has been maintained and here is certainly a standard work in the making

Medicine and Human Welfare

Henry E Sigerist, M D, Welch professor of history of medicine in the Johns Hopkins University London Humphrey Milford, Oxford University Press Pp 148 15*s* 6*d*

"The study of history is not a luxury," writes Professor Sigerist, but as his 148 pages (including 20 well-chosen illustrations) cost a pretty penny, some may not quite agree with this dictum However, under his guidance, the study of the history of medicine, if not a luxury, is certainly a pleasure The subject is approached from the aspects of disease, health, and the physician Mankind's changing attitude to medicine is surveyed from the earliest religious ideas, through the scientific to the sociological aspect He describes the salient features of the Babylonian, Assyrian, Greek, early Christian, medieval and modern schools of medicine and relates their development with man's philosophical conceptions of a changing world His brief sketch is in no sense superficial, for he has used a wide canvas and his sense of historical perspective gives meaning to the realities underlying the illusions that physicians cling to in their profession Man has gradually become conscious of the need for socialised medicine, advocates of a state medical service will find that L Mende wrote, as long ago as 1820, that "the state must protect health as its most precious property", and when we are advised, as human cobblers, to stick to our last, we may gain new inspiration from Virchow who wrote, in 1848, "The Physicians are the natural attorneys of the poor, and social problems fall to a large extent within their jurisdiction"

Professor Sigerist, of course, is writing for an American public, which has as yet no insurance against doctor's bills comparable to our National Health Insurance, but he goes much further than we have done so far in outlining a solution to the sickness problems of the population as a whole—and such problems should be the concern of all true physicians He is convinced that medicine like education will ultimately become a public service in every civilised country The scope of medicine has broadened the doctor is no longer a shaman, priest, craftsman or cleric, and he must be more than a mere scientist The new physician will be "scientist and social worker, prepared to co-operate in team work and in close touch with the people he serves, a friend and leader, he will direct all his efforts towards the prevention of disease, and become a therapist when prevention has broken down—the social physician protecting the people and guiding them to a healthier and happier life"

Effective Living

C E Turner, A M, Sc D, Dr P H, professor of biology and public health, Massachusetts Institute of Technology, and Elizabeth McHose, B S, M A, director of physical education for girls, Senior High School, Reading, Pennsylvania London Henry Kimpton Pp 432 10*s*

"To help youth discover ways of effective living" is the avowed purpose of a long and comprehensive book by two American authors The subject is considered under three heads effective living for the individual, in the family and in the community Part I deals with such matters as physical activity, food, social behaviour, care of the skin and teeth, part II with healthful living conditions in the home, and part III with sanitation and public health services The book is a mine of sound, if perhaps not always very exciting, information, it is profusely illustrated and at the end of each chapter is a searching and formidable questionnaire Much of the advice given is very proper and sensible Some young readers may feel that the exhortation not to expect too much of life is a trifle redundant at present while those who worry unduly may feel the need of something more invigorating than "if you have no control over the object of your worry, think of something else" It may well be that effective living is to be achieved by taking thought along the lines advocated in this book, but it is at least equally arguable that this desirable end is often secured by careless souls who never give a thought to the matter at all Moreover, there is a possible danger that the earnest student might devote so much attention to acquiring the necessary efficiency in living as to leave himself little or no time to live

THE LANCET
LONDON SATURDAY OCTOBER 4, 1941

COLONIAL WELFARE BEGINS ITS CLIMB

OUR colonial empire as distinct from the dependencies and mandated territories administered by the dominions is inhabited by 60 million people, two-thirds of whom live in Tropical Africa and the remainder mostly in the West Indies, Ceylon, Hong-Kong and Malaya. The colonies are administered by more than forty separate governments and are responsible for an enormous volume of trade: in 1939 the value of exports amounted to more than £4 per head of population, the imports to £3 10s. About a quarter of the average expenditure is on social services, but since the revenues in many colonies are small in relation to their size while the field of social service to be covered is very large, the sum is grossly inadequate. The Earl of LISTOWEL speaking in the House of Lords on July 9 showed how the principle of trusteeship on which the colonies are held and administered had been disregarded until 1929 when the first Colonial Development Act was passed. Even this was aimed more at relieving unemployment at home than at stimulating production of subsistence crops in the colonies. But last year, with the passing of the Colonial Welfare and Development Act, opportunities for raising the standard of living among the native populations have been greatly increased. This act authorises the expenditure of up to £5 million a year for ten years with an additional yearly grant of half a million for research. Lord MOYNE, speaking in the same debate said that but for the war the expenditure authorised might have been much higher. Last year the fall of France made it necessary to convert every available penny into aeroplanes and arms, but this year it is felt that war or no war we must not let the peoples of the colonies—many of whom already live at too low a standard—suffer from the disorganising effects of war. The obligation is the greater because the colonies have been so generous in offering us help amounting already to more than £20 million. Some have offered their surplus revenues as a gift for the prosecution of the war. Lord MOYNE uneasy about accepting these generous offers from the poorer colonies has proposed that they should be accepted as loans, to be repaid in time to come, for post-war development. The effects of the war on the various colonies have been uneven, a few produce materials which are in demand and they are in a state of unwonted prosperity especially Malaya and Northern Rhodesia, in others such as the West Indies, there has been no serious interruption of their usual economy, but a few—especially Malta and Cyprus—are cut off from their ordinary trade and some have lost their overseas markets through lack of shipping space—West Africa for example cannot dispose of cocoa and palm products, East Africa of sisal, Palestine of oranges or Jamaica of bananas. The home government has helped in these difficulties by buying up crops or financing the growers in other ways.

At the outbreak of war there was for a time a tendency towards the arrest of social programmes, but now the aim is to carry on all that were in progress and to plan ahead for others. Much of the personnel, of course, has been seconded for military service, but recruitment has been officially approved and young doctors are advised that service in the colonial empire is of as much national importance as service in the forces. The Mediterranean colonies of Gibraltar, Malta, Cyprus and Palestine are in a peculiar position at present and their medical services are necessarily subordinated to war needs. In other colonies schemes initiated before the outbreak of war are still being maintained. In Sierra Leone, for example, a campaign against sleeping sickness and yaws had been newly begun when war broke out and this is being carried on, the cost of it being £50 000 for three years. In the gold fields an attempt to get rid of onchocerciasis by evacuating the area for a time was found to be holding up gold production seriously; Mr J. J. C. BUCKLEY, D.Sc., of the London School of Hygiene and Tropical Medicine has been seconded there and is making progress in the study of the simulium fly responsible for spreading the disease. In Nyasaland Dr B. S. PLATT, a member of the staff of the Medical Research Council directed a team to make a nutritional survey and this piece of work has been continued although on a diminished scale. The M.R.C. have also cooperated in other directions, and Dr FRANK HAWKING and Dr A. J. HADDOW holding M.R.C. fellowships for research in tropical medicine worked in Tanganyika and in Kenya. Dr E. M. LOURIE, a member of the M.R.C. staff, has been carrying on research in chemotherapy in connexion with the sleeping-sickness survey in Sierra Leone which is being conducted by the local government with a grant from the Colonial Development Fund. Prof. D. B. BLACKLOCK of the Liverpool School of Tropical Medicine, and Dr. CARMICHAEL WILSON of the Colonial Medical Service, are carrying out an investigation at Freetown into the occurrence of malaria there. Dr. G. M. FINDLAY of the Wellcome Research Institute has recently made tours in East and West Africa and the Sudan to study the incidence of yellow fever and has made reports and suggestions. He has emphasised the need for further research and coördination in the African territories. Much investigation has also been going on at Entebbe under Dr A. F. MAHAFFY of the Rockefeller Foundation, the unit there having been established for several years. Many public-health measures to be effective must be on a massive scale: for example a sleeping-sickness campaign is going on in Nigeria, where a fly-free belt is being created some 70 miles long and 20 miles wide—the size (say) of Salop or Wilts. The first part of the work entails the destruction and clearance of jungle and undergrowth and is thus a considerable task. It represents one aspect of a settlement scheme, with the provision of safe water-supplies, of sanitary latrines, and of clean markets for meat and food. In Tanganyika a central development committee has been established and the study of trypanosomiasis and the tsetse fly is going on. In Northern Rhodesia a plan for establishing rural dispensaries is being continued; a new maternity block, the gift of the Beit trustees, and a pathology laboratory have been opened and there is provision for more hospitals. In British Guiana the spread of malaria and yellow fever is being investigated, with support from the Rockefeller Foundation Thanks to the work of Sir Frank Stockdale, comptroller of development and welfare to the West Indies, and his experts, a preliminary survey of nearly all the West Indian colonies is already available and plans are being put forward for various new schemes, numerous health units are being started in all these colonies Similar health units—designed to educate people in hygiene as well as to treat them—are being planned elsewhere Ceylon has been a pioneer in this direction Sir Frank has also visited St Helena, where housing is being improved and he has advised on the production of crops there In Hong-Kong there has been a large reorganisation of Chinese hospitals

Thus, taking it all round, the health and welfare services of the colonies have not been allowed to drift backwards since war broke out At the moment developmental work which requires imported machinery or essential war materials cannot be undertaken, owing to difficulties of supply and shipping and because personnel is difficult to obtain, but everything is being done to increase local industries in the colonies, to get them to undertake production of their own necessities, and to extend their internal markets They are to be encouraged to grow more foodstuffs of the right kind and to improve housing and sanitation, meanwhile the training of agricultural demonstrators, health workers and others to educate the community in matters affecting their social well-being is also proceeding All this will help to raise the standard of living Moreover Lord Moyne is encouraging the colonial governments to put forward any schemes for development, especially in social welfare, which do not require imported material, and is able to assure them that the money to finance them will be forthcoming. He is specially anxious that schemes for development should be drawn up which can be put into action as soon as the war ends Some schemes have been approved under the new act, many others are under consideration, where war exigencies allow, these no doubt will be approved This may well be the beginning of a new era in colonial government which will end for ever the charge of our enemies that our colonies are neglected estates

THE BIOPSY

The premature death of the Emperor Frederick is said to have altered the whole course of modern European history, and there is no doubt that his death from laryngeal carcinoma was accelerated because more attention was paid to Virchow's negative biopsy reports than to Ernst von Bergmann's clinical impression of malignancy, so that operation was delayed Even now, after fifty years, the limitations of biopsy have not been clearly defined and the pathologist's colleagues too often rely either too much or too little on the help he can give in diagnosis Lately surgeons, radiotherapists and pathologists have put forward their views on the value and technique of biopsy at the Faculty of Radiologists A biopsy may be required to determine the nature of the disease process, or, if that is known, to ascertain its character and so assess the best form of treatment and the prognosis, or it may be used to observe the response to treatment Even though there is seldom more than a 15% difference between expert clinical and histological diagnoses the conference agreed that a biopsy is an expedient and almost essential preliminary to treatment, but there was much discussion as to the form it should take

In small lesions of the skin mouth and breast, where the lesion is reasonably accessible and of such a size that complete local excision can be achieved this is the method of choice In extensive lesions, where a biopsy can only remove a portion of the tumour, discretion is needed If the growth is ulcerated there is little danger, though the surgeon may merely remove necrotic material impossible to interpret In cases of suspected melanoma and anaplastic growths an incisional biopsy is not advisable, and as a rule the endotherm cutting current is preferable to the scalpel It is well that in this country pathologists have educated surgeons away from the rapid frozen section When there is considerable doubt about the nature of the condition an experienced pathologist should be in the theatre, but if he cannot make up his mind on the naked-eye appearances of the tissues in situ or when excised it is doubtful if an imperfectly fixed frozen section will help him, and it is better to wait a short while until an adequate preparation can be made It is true that good preparations can be made in from 30 seconds to 6 minutes, but these methods are seldom adequate for the difficult case, there are numerous tricks which can be employed to accelerate the production of satisfactory sections, many of which are described in a new book by Krajian[1] In regions not readily accessible to direct excision it is usual to use biting forceps and excise a portion of the growth This is the routine method employed for growths of pharynx, bronchus, œsophagus, rectum and bladder, but it is open to the disadvantage that a very small fragment is removed, difficult to interpret and not always from the most suspect area

In deep-seated lesions there is a further possibility—the aspiration biopsy This method was first used by Kuss[2] in 1847 but was reintroduced about ten years ago and is gaining favour as a simple outpatient procedure The technique is simple the skin area is infiltrated with local anæsthetic or a small dose of Evipan is administered and then a syringe with a wide bore (No 18) needle is introduced into the tumour, the piston is withdrawn fully and the needle pressed further into the tumour, the direction of the needle is then changed to cut off the column of tissue in the needle, the tension on the piston released, and the syringe withdrawn The thread of tissue may then be smeared on a slide and treated by Dudgeon's method[3] or embedded in paraffin and sections prepared The advantages of the technique are obvious and the dangers apparently slight, but it requires close collaboration between the surgeon and pathologist Barringer[4] and McGavin[5] have advocated its use in the diagnosis of prostatic carcinoma, while Russell and Cairns[6] have proved its value in cerebral pathology where the Dudgeon smear method enables a diagnosis to be made in a matter of minutes At the Radiologists' conference, both Dr Frank Ellis and Mr T A Green strongly supported it, and Ellis claimed that it would give reliable results in 70% of cases, though from his figures it is not clear what proportion of cases in which an unsatisfactory or negative aspiration was obtained were subsequently shown to be malignant When it is impossible to obtain material by aspiration a punch biopsy with the aid of a trocar may be used and GREEN has devised a modification of this instrument which seems to have some advantages These methods seem unfortunately to be least satisfactory in breast tumours, indeed CUTLER[7] has said that the hazards and uncertainties of the technique do not justify its use in the diagnosis of borderline breast tumours Sternal-marrow and splenic puncture are used to good effect by the hæmatologist and to an increasing extent by the bacteriologist but the dangers of hepatic biopsy[8] outweigh its value and the "ponction triple" of EMIL WEIL has not found many supporters Nor can aspiration be recommended in lymph-node enlargements, although good results have been claimed, for a satisfactory interpretation of a lymphadenopathy it is essential to have a node from a site of election carefully excised and prepared and examined by the best histological technique Lately VAN ORDSTRAND and LAMBERT[9] have urged the more extensive use of aspiration biopsy in non-tuberculous infective lesions or neoplasms of the lung and pleura Turning to uterine pathology, cervical tissue is removed by cautery or biting forceps, and in most hands Schiller's iodine test has not proved reliable, in the uterine cavity curettage has been in use since the days of MUNDÉ, yet the suction curette[10] which has reduced the operation to an outpatient procedure without decreasing its diagnostic accuracy has not yet received the support it deserves The battle has been waged most furiously in the realm of bone pathology YOUNG[11] decides strongly in favour of an open biopsy of adequate size in every case of suspected bone sarcoma, and has shown by experiment that aspiration methods are perilous as well as giving uncertain results

The biopsy having been achieved and the tissue judged to be malignant, the pathologist has then the responsible duty of assessing its degree of malignancy and probable response to treatment His opinion cannot rest on cytological criteria alone but must be guided by his knowledge of the natural history of that particular type of growth in that situation This requires close collaboration between the laboratory and the follow-up clinic, and it is to be hoped that this aspect will be considered by local authorities when they are implementing the Cancer Act The statistics being collected by the clinical cancer committee of the British Empire Cancer Campaign will prove of great value in this respect and no doubt correct many vague clinical impressions Nevertheless, cytological analysis is of considerable value and many forms of classification have been suggested, that of BRODERS[12] is the most widely used and forms a useful histological shorthand CATHIE[13] brought forward experimental and clinical evidence to suggest that the amount of residual ash in a microincinerated section was a reliable index of the radio sensitivity of neoplastic cells and this method of assay should be further investigated At the Faculty of Radiologists Dr F G SPEAR described a method in which the proportions of resting, dividing, differentiating and degenerating cells at the growing edge of the tumour are assessed and he suggested that they might prove a useful index of the response to radiotherapy, this is clearly a rational method of measurement but must be laborious if it is to be reliable

The risks of biopsy must be borne in mind The danger of causing metastases by neoplastic cells forced into lymphatic or vascular channels has been exploded by both clinical and experimental experience, though there is a possibility of implanting neoplastic cells in the healing scar of an incisional biopsy, yet if the tumour is found to be malignant then a radical operation should follow before this can be significant There is, however, a psychological risk in an incisional biopsy, the patient may agree to this and yet refuse the second radical operation in spite of all advice and procrastinate until a radical operation is impossible The difficulty is unlikely to follow the comparatively simple aspiration biopsy, and although implantation along the track is possible this can be reduced if a diathermy punch is used The chief danger of the aspiration biopsy is hæmorrhage either into the tumour itself or as the result of puncture of an adjacent vein, this may be serious and is always alarming, yet it is the experience of those who execute the method that it is relatively infrequent

It is clear that the aspiration biopsy or an analogous procedure should be used more freely, but before a surgeon resolves to try this diagnostic method he should consult with his pathologist to ensure that the specimens are submitted for examination in a suitable manner, otherwise he may be disappointed.

Annotations

VALUE OF RABIES IMMUNISATION

THOUGH genius by its intuition may open up limitless fields for discovery it may at times clog the wheels of progress, for the disciples of a genius are too ready to regard any questioning of the master's words or deeds as sacrilege Thus until the last few years, and despite the fact that it has been practised all over the world, there has been no serious attempt to determine whether antirabic immunisation is really of any value On July 6, 1885, Pasteur announced the successful use of a prophylactic vaccine on a boy, Joseph Meister, who had been bitten fourteen times by a mad dog The scene has been immortalised by the statue which now stands in the gardens of the Pasteur Institute in Paris, but Meister's cheery smile will no longer greet those who seek their letters in the concierge's lodge, for Meister committed suicide soon after the German occupation The institute's figures show that the fatality among the treated patients fell from 0 9% in 1886 to 0 3% in 1890, it varied between 0 2 and 0 35% for the next 30 years, while since 1922 it has been zero, except in 1924[1] According to McKendrick's reports[2] from various Pasteur institutes the fatality from rabies after vaccination with various vaccines has ranged from 0 23 to 0 49% Denison, McAlpine and Gill[3] reported 21 fatal cases of rabies among 34,864 vaccinated people in Alabama (0 06%) from 1922 to 1936 On the other hand, it is possible that the value of the Pasteur treatment has been overestimated Denison and Dowling[4] for instance, reported 48 cases of rabies in nearly half of which prompt and adequate prophylactic treatment had apparently been given Ratcliffe[5] found that of 40 fatal cases of rabies 12 had received Pasteur treatment Yu[6] has lately recorded that from July, 1923, to August, 1940, 383 patients attended the medical department of Peiping Union Medical College because of dog bites, of this series 201 were vaccinated and 182 were not, either because they refused or because they were bitten by dogs which were proved to be normal Among the 201 vaccinated people there were 9 (4 5%) cases of rabies, among the 182 unvaccinated 18 (9 8%) In 2 of the vaccinated people in whom rabies developed vaccination was started a fortnight after the bite, possibly too late The failure of the immunisation could not in the others be ascribed either to delay in treatment or to severity of the wounds, neither could the viruses obtained be identified as reinforced viruses in the sense used by Koritschoner, although in all the cases the first symptoms appeared within 14 days after inoculation and the viruses isolated became fixed after from 3 to 10 passages Even when no cases of rabies develop the value of the Pasteur treatment is not absolutely proved Thus in Shanghai Lieou[7] reported that 402 complete Pasteur treatments were given from 1937 to 1939, no case of rabies was observed However, of the supposedly rabid animals 249 were definitely proved to be free from rabies, 106 were suspected on various grounds of having rabies, 10 had clinical symptoms of rabies and only 37 were proved experimentally to be rabid Of the 37 people who were associated with the animals proved to be rabid only 17 were actually bitten, 9 had had their hands covered with saliva and 11 were licked by the rabid dogs It is known that rabies can be contracted by contact with the saliva of a rabid animal but there is little or no evidence to show how often this happens, while according to Kelser[8] only about 25% of people bitten by rabid dogs actually develop rabies It seems then that in less than 5 out of 402 patients is there any actual proof that rabies was prevented Similarly 442 people received the Pasteur treatment in Paris in 1937 but in only 2 instances was the diagnosis established by histological examination of the dogs' brains Before the value of the Pasteur treatment can be fully assessed much further work will have to be carried out both experimentally in the laboratory and in man Statistics must be based only on cases which can be proved to have been bitten by rabid animals, while the characteristics of the viruses isolated must be carefully studied If after thorough investigation the present method of immunisation is found to be inadequate it should be scrapped Pasteur would be the first to encourage us to find a better

JOINT RENOVATION

ANY contribution is welcome that tends to lessen the feeling of helplessness in dealing with severe osteoarthritis Magnuson's[9] results with operative treatment based on purely mechanical considerations are particularly encouraging He confirms the experimental findings of Bauer and Bennett[10] that the pathological changes are probably the result of frequent minor traumata and that the typical marginal exostoses are produced in the effort to stabilise a joint which has suffered ligamentous injury or damage to articular cartilage Once these exostoses are formed they limit movement and a vicious circle of recurrent trauma and new peripheral bone formation is set up Clinically, operation aiming at complete removal of mechanical irritants from the joint surfaces was performed on 62 cases with entire relief in 60, no formal synovectomy was carried out since this does not appear to be called for in non-rheumatoid cases In the hip, where old Perthes's disease or slipped epiphysis is often the primary lesion, removal of marginal osteophytes and the overhanging acetabular lip gave gratifying results, in the elbow, after wide exposure with reflexion of the olecranon, the smoothing down of transverse ridges lying in the sigmoid notch was often necessary The knee was most commonly involved and an extensive toilet is advocated in which the condylar margins are excised, all degenerated cartilage removed down to firm fibrocartilage or eburnated bone, the menisci dealt with if injured, and the patella shaped with the chisel to glide unobstructed between the femoral condyles Movement was begun on the fourth post operative day, with gentle passive encouragement and muscle re education, and weight bearing by the tenth day It is then of cardinal importance for the patient to hold the joint quite straight and to use sticks only, the pain of walking on the slightly flexed knee or the use of crutches will defeat the surgeon's endeavours Magnuson's results give point to the observation of Kelikian[11] that trauma and trauma alone is the primary affection of articular cartilage and that metabolic or endocrine factors are only secondarily associated with osteo-arthritis They are encouraging, too, since operations of this type, as opposed to arthrodesis or arthroplasty, have not been very popular It may well be that such a careful removal of mechanical irritants is better than a formal synovectomy or capsulotomy, or the casual removal of osteophytes, but the operation is not a minor one and, unless the patient gives whole hearted cooperation, may leave him worse than before

FIBROIDS

IN reviewing the cases of myomata treated in their wards Mahfouz and Magdi[12] of Cairo discuss almost every aspect of this common tumour including the history of its surgery Avicenna in the 11th century described and advocated the excision and avulsion of vaginal polypoid myomata with or without ligation of the pedicle, and he seems to have been the first to approach the problem of myomata from a purely surgical standpoint All sorts of procedures were tried by the earlier surgeons, including ligation of the uterine vessels and ovarian castration, in an effort to diminish the blood supply to the tumour The name of Lawson Tait will always be associated with this latter procedure, he claimed that the "whole merit of the thing, however much or little it may be, belongs to British surgery," for there was considerable competition from the United States and the Continent to establish a prior claim for its invention and successful performance Tait's first successful ovarian castration was performed in 1872 A few years before this, in 1863, Spencer Wells had performed the first two abdominal myomectomies, and in the same year Charles Clay of Manchester performed the first successful supravaginal hysterectomy in Europe Clay ligated the whole uterine stump with three strands of Indian hemp and only took fifteen minutes for the whole operation The patient left hospital 35 days later

In their series of 931 cases of myoma all treated by operation Mahfouz and Magdi note some interesting facts 86% were multiple, 14% single, 58% intramural, 24% submucous and 18% subserous, only 2% were cervical in situation Ovarian cysts were associated in 16% of their cases and inflammatory disease of the adnexa in 28% This latter complication they regard as a serious one in that it considerably increases the fatality, the commonest cause of death being peritonitis in 52% of he fatal cases Axial rotation of the tumour occurred ı 5 patients, the cause being a pedunculated subserous broid Various degenerations were noted in 18% f the tumours removed and red degeneration in 6 cases n 3 cases the tumours had become detached entirely rom the uterus and gained a new parasitic foothold on he omentum Malignant degeneration was encountered n 3 cases—a low incidence, for in England the generally ccepted figure is 1% The operations performed were ubtotal hysterectomy in 459 cases with 9 deaths, bdominal myomectomy in 362 cases with 5 deaths (a ery creditable achievement, for myomectomy in this ountry is recognised to carry a fatality of 5% and subtotal hysterectomy 2%), vaginal myomectomy in 93 ases with 4 deaths (this high fatality is explained by the arge infected masses impacted in the vagina after years of ill health and hæmorrhage), and finally total hysterectomy in 18 cases with 3 deaths (a high figure, explained as due to tubo ovarian infection resulting in peritonitis) The number of myomectomies is large The reason for this in Egypt is largely a social and religious one, for fertility is of tremendous importance there, but at the same time *it does the surgeons concerned great credit* for holding a conservative outlook Here Victor Bonney has preached just such a doctrine for years Its soundness is illustrated by one of the cases in the Cairo series, a woman of 38, married ten years without issue, in whom they enucleated 52 myomata This lady was 16 months later delivered of an heir. How many surgeons would have sacrificed the uterus? Mahfouz and Magdi put the recurrence figure after myomectomy at 5% They regard the operation as dangerous if the cavity of the uterus has to be opened or if multiple incisions are needed for the enucleation of many tumours The incidence of stump carcinoma in the cervix after subtotal hysterectomy was nil The work of these two surgeons is a strong plea for conservatism and a wider adoption of myomectomy whenever myomata are encountered in a uterus that is still potentially capable of being impregnated They undoubtedly favour the subtotal operation as against the total in hysterectomy and this will give many English and American gynæcologists food for thought

MEDICAL REPORTS AND CERTIFICATES

THE legal position and usual practice with regard to medical reports and certificates is succinctly set out in memorandum No 156, issued by the Central Bureau of Hospital Information[1] Legally neither a hospital nor its medical staff is obliged to give reports or certificates o any third party outside The only legal method of xtracting information from the medical officer is to ubpœna him to give evidence in a court of law This loes not oblige him to say anything to anyone outside he court, and even in court he can object that the nformation is confidential, although the tribunal may lecide to overrule his protest that disclosure would be a breach of professional secrecy The patient's consent hould always be obtained before giving a report or ertificate, one large London hospital refuses all reports nless application is made on a particular form (appended o the bureau's memorandum), this form contains a pace for the patient's express consent in writing

The memorandum usefully sets out the usual practice bout fees Hospitals generally allow a medical officer o receive the fee charged for a report, they sometimes ollect the fee for him The fee does not commonly xceed two guineas, it may be less (according to the ircumstances or the patient's means) or nothing at all n road accident cases one large London hospital charges fee of two guineas to an injured patient who wants a edical report to support his claim for compensation his fee is collected only if the claim succeeds (presumably because in that case the plaintiff recovers it from the defendant), it is then handed over to the medical officer who made the report; if the claim fails the hospital itself pays the doctor a fee of 10*s* 6*d* Where a patient wants a medical certificate in order to recover newspaper insurance compensation, the fee is usually 5*s*, as the amount recovered is small Where a medical certificate (usually the confirmatory certificate) is given by a hospital medical officer under the Cremation Regulations, the usual fee is a guinea It may be recalled, in passing, that regulation 8 of the 1930 regulations, requiring certificates from the deceased's medical attendant and the confirmatory certificate from another practitioner, is suspended by Defence Regulations where the registrar has certified that death has been registered as due to war operations Hospitals sometimes charge 1*s* for "admission and discharge certificates, more often they are given free Nor is it usual to charge for an "unfit to work" certificate Forms of "unfitness to work" and "admission and discharge' certificates are appended to the memorandum There is also a simple form of general information *certificate* *This is useful* where a rough idea of the disability is needed, rather than the medical details—for example, where a workman is in hospital and the employer wants to know whether the injury is so serious that another workman had better be engaged in his place

HISTIDINE AND HISTAMINE

SUBSTANCES which give specific chemical reactions are much more easy to follow and investigate than those which do not, and this generalisation is well illustrated by the amino-acids Most of those with closed rings or unusual chemical groupings in their molecules can be induced to react in some way which betrays their presence whatever the circumstances, and this has favoured their isolation and investigation Those with straight chains are much more difficult to characterise, and, although progress is always being made, much less is known about their occurrence and distribution Indeed threonine was only detected, and that quite recently, because an elaborate investigation led to the discovery that rats would not grow on a synthetic mixture which did not contain it The amino-acid which is known to the biochemical fraternity as histidine and to their purer chemical cousins as β-iminazole-α aminopropionic acid gives colour reactions with bromine which enable it to be detected and estimated in minute quantities in the body fluids; and histamine, the primary amine formed from it by decarboxylation, has equally striking pharmacological properties by which it can be traced Both these substances have been stated to occur in urine, and their presence there has recently been proved by elaborate checking and rechecking of the methods by which the compounds were first detected and estimated. It has been shown that histidine[1] is a constituent of normal urine, and up to 80 mg per 100 c cm have been found there Larger amounts are excreted during pregnancy The quantity depends partly on the subject and partly on the food, and although there are other factors regulating this excretion which have not been exactly defined the histidine appears soon after conception and its elimination seems to be related in some way to the increased excretion of the gonadotropic hormones Pregnant animals do not excrete histidine in this way—a good example of the biochemical differences which exist between animal species and add such zest to comparative physiology During the severe toxæmias of pregnancy histamine is excreted, it must be formed from histidine but why the toxæmias should bring about the appearance of this highly reactive body, and whether it plays any part in the production of the toxæmic syndrome is still obscure It is evident that we have still much to learn about histidinuria and histaminuria, and furthermore, we know nothing at all about the excretion of all those other amino acids which we cannot readily detect and estimate Taking the normal range of histidine excretion to be up to 80 mg per 100 c cm of urine, this amounts to more than 1 g per day—quite a large quantity of a valuable and essential bodily constituent We know of no syndrome due to histidine deficiency, but this rate of loss suggests that such a thing is not inconceivable

FRACTURED MANDIBLE

In the last war and up to now in the present one the treatment of fractures of the mandible at or posterior to the angle has presented insurmountable difficulties when the patient has no teeth Here, as in other fractures, correct apposition of the ends of the broken bone is the first essential to bony union, and such apposition is very difficult to attain because when the fracture is far back in the region of the last molar the small posterior fragment is drawn upwards and inwards towards the midline by the pterygoid and temporal muscles The many ingenious appliances so far devised have mostly failed to keep the ends together, so that the patient has been left with fibrous union and deformity Moreover, they usually entailed immobilisation of the jaw leading to difficulties in feeding and delayed union from prolonged lack of function Last November Vaughan Tomey suggested to the central counties branch of the British Dental Association in Birmingham that external splinting might be feasible, and the two papers published in this issue demonstrate that it is Dr Pohl grips the fragments with hook-screws of his own design and welds the screws together by an external metal bar Mr Rainsford Mowlem and his colleagues at Hill End maxillo-facial unit use crossed Kirschner wires inserted into each fragment, and fix them by an external clamp Pohl has applied his technique to one case, the other has been used in 19 Both have the advantage of allowing some measure of mastication as soon as the splint is applied

A SOCIAL DIAGNOSTICIAN

Diagnosis must come before treatment, and in his second examination[1] of the symptoms of social ill in York, Mr Seebohm Rowntree once more, as in 1899, diagnoses poverty as their cause In his preface he disclaims any wish to prescribe for the disease, contenting himself with a masterly picture of the syndrome He discusses the remedies that lie to hand, but leaves the choice of treatment to others He has made his diagnosis on the result of a house to-house visitation of over 16,000 families—almost the whole working-class population of York—and in a chapter, which he modestly assumes will interest only the statistician, he compares his figures with those which might have been obtained by the more usual sampling methods Mr Rowntree's technique gives an objective picture of the economic situation of the city, of its housing, of its public-health and education services, and of the leisure-time habits of its inhabitants He found that the proportion of the working class population living in abject poverty has been reduced by more than half since 1899, but that rather more than half of the working-class children under one year of age were still living below the poverty line, 47% of them would probably remain in poverty for five years or more, and 31% for ten years or more Yet Mr Rowntree's standards of poverty are not indulgent He has taken as his criterion for a man and wife with three children a minimum income of 43*s* 6*d* after rent and rates are paid

But during the last forty years there has been progress as well as poverty Housing in York shows a persistent upward trend, and both social and public-health services have increased to a remarkable extent The chapter
on health records a fall in the general death-rate
and in the infant mortality of two thirds, but ev
infant death-rate was nearly twice as high in th
class as in the highest class of those inve
Reduced working hours combined with
facilities for recreation have led to widened

NUTRITION OF RURAL CHILDREN IN WAR-TIME

DAGMAR CURJEL WILSON
M D GLASG, M R C P, F R C O G, D P H
WOMEN'S MEDICAL SERVICE, INDIA (RETD)

IN December, 1939, and January, 1940, I obtained records of the state of nutrition of a group of children who might be expected to continue to live in the same neighbourhood It seemed possible that war-time diet might prove detrimental to health, and that such records would prove useful for comparison Schools were chosen for the survey since growing children show evidence of dietary deficiency more readily than adults Children of rural Oxfordshire were selected as suitable, children from the evacuated areas being carefully excluded

Overcrowding of the schools by evacuees hampered examination, so the tests used were limited to those which previous nutritional surveys[1] had shown to give close correlation with nutritional deficiency The following definite and easily recognised signs of vitamin deficiency were sought follicular hyperkeratosis (phrynoderma), xerophthalmia and keratomalacia, angular stomatitis (cheilosis); congested gums (purple discoloration or bleeding), rickets (including the lesser degrees of enlarged epiphyses and bossing) Assessment of the state of nutrition was also made according to the standards of the Board of Education (Health of the School-child, 1937) Such assessment is largely subjective, but when all the children are examined by the same observer results are obtained which are useful for comparison Dental observations (decayed, missing and filled rates) were made and special points of clinical interest were also noted

Visits were paid to 41 different places in Oxfordshire, 1568 children were examined, 531 aged 6–7 (group A), 508 aged 10–11 (group B) and 529 aged 13–14 (group C) Fourteen months later the same schools were revisited, some children had meantime moved to senior schools and others had left school on reaching the age of 14, but it was possible to examine 499 children again—316 in group A and 183 in group B The numbers of group C remaining were too few to justify comparisons The results of the two surveys are compared in table I

TABLE I—STATE OF NUTRITION OF 1568 SCHOOL-CHILDREN IN DECEMBER, 1939, COMPARED WITH THAT OF 499 OF THEM IN FEBRUARY, 1941

Group	When examined	Total	Boys	Girls	Signs of vitamin deficiency: Phrynoderma	Xerophthalmia	Cheilosis	Congested gums	Rickets	Nutrition: Excellent	Good	Subnormal	Bad
										%	%	%	%
A*	Dec. 1939	531	260	271			4		27 (5%)	32	58	10	0
	Feb 1941	316	145	171			1		6¶ (1·8%)	29	58	12	0
B†	Dec 1939	508	259	249			5		19 (4%)	29	59	12	0
	Feb 1941	183	95	88			3§			35	53	12	0
C‡	Dec. 1939	529	286	243			4		9 (1%)	37	57	5	0
	Feb 1941	Too few to permit of comparison											

* A (aged 6–7 in Dec 1939) † B (aged 10–11 in Dec 1939)
‡ C (aged 13–14 in Dec. 1939) § All new cases ¶ 3 new cases

If the 499 children who were examined twice are considered separately, there is no evidence of significant deterioration in their nutrition after fourteen months, that is, there has been no increase in signs of vitamin deficiency and no falling off in the state of nutrition as assessed by the same observer At the outset and during the period of inquiry the existence of a slight degree of dietary deficiency was indicated by the occurrence of cases of cheilosis and of low grade rickets, but the incidence of these did not increase significantly (table II) Indeed, although the number of cheilosis cases was slightly higher at the second examination the number of cases of rickets was noticeably lower, even allowing for the expected decrease in signs of rickets with advancing age of the child It seems probable that more signs of deficiency would have been found but for the widespread adoption of the county school-milk scheme Throughout the investigation most of the children were receiving ⅓–½ pint of milk daily in school, an amount which though not sufficient to ensure a high standard of health might prevent open clinical signs of deficiency

During the inquiry visits were paid to the homes of families in different villages It was found that the diet of some of the poorest households had actually improved, thanks to more regular wages or allowances received by the father on changing from low-grade agricultural work or casual labour to war-time duty Inquiry in the homes of rachitic children showed that they belonged to large families where the mother had apparently given up the struggle of trying to make ends meet satisfactorily on a low income, often more than one child showed signs of rickets

TABLE II—INCIDENCE OF RICKETS AND CHEILOSIS IN THE 499 CHILDREN EXAMINED TWICE

—	Examined	Cheilosis	Rickets
Group A	Dec 1939 Feb 1941	1 1 (same case)	20 6 (3 new cases)
Group B	Dec 1939 Feb 1941	2 3 (all new cases)	8 Nil

The occurrence of cheilosis among these Oxfordshire children is of interest because this clinical sign of riboflavin deficiency has not hitherto been sought during school health inspection in England Cheilosis—as evidenced by white sodden excoriation at the angles of the mouth—was noted in 17 of the 1568 rural children examined during this inquiry It was present in 13 of those seen at the first examination and 4 of those seen at the second examination Of 13 cases revisited 11 cleared up without treatment within a period of eight weeks, 2 cases of greater severity did not improve spontaneously, and at the end of eight weeks were treated with pure riboflavin Both these children belonged to large families of low-grade agricultural labourers The most severe case, in a girl aged 13, healed after treatment with riboflavin 30 mg over a period of thirty days, but relapsed three months later, and required an additional 40 mg of riboflavin over twenty-four days for cure The second case, in a boy aged 6, was less severe and was cured by riboflavin 20 mg over twenty-three days, and remained free of symptoms during four months' subsequent observation He had been recognised as undernourished at routine school medical inspection, and was receiving 1 pint of free milk daily at school The presence of riboflavin deficiency, in spite of such a daily milk consumption, may be explained by the low riboflavin content of milk at certain seasons[2]

SUMMARY

The nutritional state of 499 rural Oxfordshire school-children was determined in December, 1939, before the introduction of rationing, and again in April, 1941, after more than a year of dietary restrictions There was no sign of increasing nutritional deficiency and no deterioration in the state of nutrition as assessed by the same observer Some degree of deficiency of the vitamin-B_2 complex was present throughout the period of observation as indicated by the presence of 17 cases of angular stomatitis (cheilosis) among 1568 children between the ages of 6 and 14 Pure riboflavin was successfully used to treat 2 cases

I am indebted to the education committee of Oxfordshire county council for access to the schools, and to Dr H C Jennings, county medical officer of health, for the assistance of health visitors in home visiting Pure riboflavin was provided by Messrs Roche Products

MEDICINE AND THE LAW

Punishment for Bogus F R C S

UNQUALIFIED practitioners who are guilty of sheer fraud will attract little public sympathy On June 23 James Leroy McCune, aged 40, described as a physician, of Alma Square, St John's Wood, was arrested on the charge of wilfully and falsely pretending to be a physician He was subsequently charged at Marylebone with wilfully and falsely pretending to be a Fellow of the Royal College of Surgeons on June 24, with a further similar charge relating to Aug 29 A detective sergeant informed the magistrate that he found a car, with the word "Doctor" on the windscreen, outside the accused's address on a door-post was the visiting card "James L McCune, M D M A , F R C S" Told that he would be charged with pretending to be a physician McCune replied "I am" Documents bearing the name "Dr McCune" were inside the car He had examined a boy on June 23 who was suffering from hay-fever and had told the boy's grandmother that he was suffering from congestion of the lungs and eye trouble, and that, if not taken care of, he might have T B The boy had neither of these diseases Writing to the patient's grandmother, the accused signed himself "James McCune, F R C S , physician and surgeon" He pleaded guilty He had 20 previous convictions in Australia and two in this country , 17 were offences of dishonesty McCune said he put the label on his windscreen to avoid being questioned about petrol rations He had obtained no financial benefit by posing as a doctor The police witness did not agree with this statement , there was a warrant against the accused at Edinburgh over the purchase of a practice It was also said that, being a married man with two children, he had been posing as an unmarried man and associating with a 21-year-old unmarried woman from whom he had borrowed £20

Mr L R Dunne fined him £60 or two months' imprisonment, and refused to allow time for payment of the money It was always a serious matter, said the magistrate, for an unqualified person to hold himself out to be a qualified medical practitioner , but it was much worse when the person was a man of bad character

Child's Death in Hospital

We noted lately in this column an allegation of delay in treating a child admitted to a Manchester hospital for serious burns The Manchester public health committee appointed a subcommittee to investigate the occurrence The subcommittee's report, adopted by the full committee, disposes not inadequately of the complaints which had led the coroner to criticise those concerned
